Source record: 21334

The red core is your AM oscillator coil; the yellow is the 1st, the white is the 2nd, and the black is the 3rd I.F. transformers respectively. The brown, blue, orange, and green core units are your 10.7MHz I.F. transformers.

Pete

3. NIST Makes Astounding Discovery

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-01-01 13:38:44 UTC
From: n2ey@aol.comSPAMNO
Message-ID: <20050101083844.10298.00000325@mb-m25.aol.com>
Source record: 21336

NIST scientists have figured out that Morse code may get through poor transmission conditions when voice does not.

"...first responders may be able to receive and see simple patterns—like Morse code—from a survivor repeatedly turning a radio or phone on and off, in cases where the signal was too weak to receive audible voice messages."

http://www.nist.gov/public_affairs/releases/demolition_dcconv.htm

What's "better" mean? How much better is "good enough"? How much more will
the "better" stuff cost?

I'm with you there.

The logical thing would be to develop a digital system (after all
morse is digital) that would appear as text (so non-operators could
grok it), and with variable transmission rates to get the message
through - auto repeat? (and/or lots of abbreviations).

Then test it on some blown up buildings.

But if I were the NIST "scientist" would my primary goal be to solve
the problem or make money studying it?

7. Re: FET amplifier (theory != measurement)

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-01-02 00:14:42 UTC
From: Gary Morton <gary@alma.demon.co.uk>
Message-ID: <41D73D10.2050607@alma.demon.co.uk>
Source record: 21340

Roy,

many thanks for taking the time to compose such a detailed reply.

I continued to experiment and make some more measurements, but I got sidetracked into finally constructing a simple SSB receiver. I then got side tracked into trying to figure out why the radio doesn't work very well. Even the damn 2N3819 FET oscillator didn't work! I even tried different FETs. That was fixed by adding extra source resistance.

The following table may not look right as it appears to have tabs in it.

vga in V
idd in mA
gm in ms
Rs in ohm
Rdrain
0.0 13.2 n/a 0.0 n/a
-0.2 12.1 5.1 17.6 196.35
-0.5 10.5 4.8 51.3 207.54
-0.7 9.6 4.4 77.0 227.01
-1.2 7.8 4.3 149.7 231.31
-1.5 6.4 4.2 227.1 240.46
-1.8 5.1 3.8 348.9 260.87
-2.1 4.1 3.5 498.8 284.05 <- operating point
-2.5 2.6 3.2 984.4 312.25
-2.9 1.6 2.5 1781.3 398.94
-3.3 0.7 1.8 4808.8 541.10
-3.6 0.1 n/a 26000.0 n/a

I'd never heard of the effect of "effective drain resistance". I can't recall seeing it explained in any of the texts which I have read. Mind you the PW article suggested that the graph of Id vs Vgs was a straight line for smaller values of Vgs! I re-calculated Rd using this extra value but I just got a less than unity amplifier.

It seems to me and you seem to back this up the a FET buffer whilst a useful impedance converter also distorts the signal due to the x squared function. This makes it good for mixers though. I do often see FETs used as buffers for VFOs in simple rx designs.

Anyway I'll do some more experimenting until I get theory and practice to match.

BTW I have already played with Spice, using it to plot various curves (Vd vs Id for various Vgs, and Id vs Vgs). I have also simulated FET amplifiers and buffers. Now I need to change the 2N3819 model to match the "slope" of my FET and see what the simulator gives.

regards...

When Morse failed to get through, the locally-based branch of a mutlinational
oil produced resorts to ...

FAX. Write the message with a broad-tipped felt pen and send radiofax.
Worked for them. Usually their last Morse transmission as conditons
deteriorated was "send fax ... send fax ..."

Hi Fella's

Would any of you know what the semiconductor replacement types are for this powersupply? All the transistors and diodes. IC1, Q1, D5, and the TO-3 pass transistor on the back. I have the bridge diodes already. I trashed something but I don't have a manual and am just trying to take a shortcut. :-).

Thank you in advance.

One of the local hams here is also a pilot instructor, while flying one day the mic on his aircraft radio broke. Being a long time brass pounder he took the mic apart and made a key out of it.

Luckily one of the people in the tower that day knew morse and was able to understand Mike's messages to the tower.

Lucky for them that aircraft band was still am so Mike had a carrier to turn on and off.

Nothing is 100% reliable. You never know when you will be faced with using broken or impaired equipment so you have to be prepared to improvise.
thanks, John.

This is typical of the sort of babble you would expect from the land of fruits and nuts.

Even if dollars were unlimited, there is no such thing as 100% reliability in anything. And to get significantly closer than they are now requires other prices besides just dollars. How much weight do you want these guys to carry? How much RF radiation do you want to expose these emergency workers to? How big and cumbersome a thing do you want them to have to deal with while they are crawling around an emergency scene? How much care and feeding is this magical equipment going to take? How much complexity do you want them to deal with to disctract from their day job of saving lives?

Even if the problem could be solved by throwing dollars at it, it's basically a zero sum game. I realize that Californians think taxes are wonderful, but most of us have plenty enough taxes thank you. If I recall they were talking about DHS people here mostly, so should we cut down on airport security so we can have more hijackings, or maybe we should cut back on emergency relief to earthquake victims.

This is exactly why we attach a dollar value to saving lives, as unappealing as that exercise is. If we don't do it, we stand to kill ten people to save one. Bad plan.

..

16. Anyone familiar with these parts? e.g. VTW 45.3

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-01-03 19:14:02 UTC
From: Bill K <kirklandb_nospam@sympatico.ca>
Message-ID: <ZJgCd.4310$7n1.268559@news20.bellglobal.com>
Source record: 21349

I have a box full parts labeled with a 3 letter prefix starting with V.

E.g.

VNX 11.5
VSK 11.8
VSM 12.1
VTK 29.4
VTW 45.3
VTX 46.4 labeling on part is : A50 VTWD A402

Anyone have any idea what these are and what the specs are?
They seem to be a precision capacitor as some of the box labels indicated
"pf". I put some on the capacitor meter and get the appropriate reading,
e.g. a VTW 45.3
has 45 pf.

18. FS: Old Radio-Related Books, 1929-1980

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-01-03 20:23:21 UTC
From: oldbooks78@aol.com
Message-ID: <20050103152321.11818.00002620@mb-m16.aol.com>
Source record: 21351

I currently have the following old radio-related books for sale. Postage (Media Mail within the US) is $2.50 for the first book and $1 for each additional item. The books are:

"Reference Data for Radio Engineers," 2nd Edition, by Federal Telephone And Radio Corporation. Federal Telephone and Radio Corporation, 1946. The 322+ page hardbound book is in about very good condition, clean with no page tears or pen marks except for a previous owners name stamp inside the covers. Green cloth covers. A nice early radio reference text. Available for $7.

"Practical Radio Communication; Principles, Systems, Equipment, Operations" by Nilson, Arthur R. And J.L. Hornung. McGraw-Hill, 1943. Second edition. The 927 page hardbound book is in very good condition, clean with no page tears or pen marks except for a preperty stamp inside the front and rear covers. A nice early radio text. Available for $8.

"Basic Radio, the Essentials of Electron Tubes and Their Circuits" by Hoag, J. Barton. D. Van Nostrand, 1942. Fifth edition. The 379 page hardbound book is in very good condition, clean with no page tears or pen marks except for a previous owners name and address inside the front cover. Tight binding. A nice early radio and electron tube text. Available for $9.

"Communication Engineering" by Everitt, William Littell. McGraw-Hill, 1937. The 727 page hardbound book is in about very good condition. Clean with no page tears or pen marks except for a previous owners name and address inside the front cover, and a few passages underlined in pencil. A nice early text on the science of the radio. Available for $8.

"Radio Engineering Handbook" by Henney, Keith (Editor), McGraw-Hill, 1950. Foueth Edition. The 1197 page hardbound book is in very good condition, clean with no page tears or pen marks except for a previous owners name inside the front cover, and their initials on the upper page ends. Otherwise a very clean copy. Available for $9.

"Reference Data for Radio Engineers, 1st Edition" by Federal Telephone And Radio Corporation. Federal Telephone and Radio Corporation, 1943. First edition, second printing. The 200 page hardbound book is in good+ condition, clean with no page tears or pen marks except for a previous owners name inside the front cover. The pages are a bit wavey along the bottom edge, possibly from minor moisture exposure. Otherwise very nice. Green cloth covers over flexible boards. A nice early radio reference text. Available for $10.

"Instructions for Operation of 6 Tube Superheterodyne Receiver Model 5002" c1940. A 4 page instruction for operations for the Superheterodyne Receiver Model 5002. Not dated, but looks to be from the 1940's or so. The rear page of the instruction sheet is a schematic diagram for the receiver. Available for

$8.

"1933 Report of the Standards Committee of the Institute of Radio Engineers" by Institute Of Radio Engineers, 1933. The 225 page softbound book is in good+ condition, clean with no page tears or pen marks except for a previous owners name on the front cover. Some wear to the spine paper, but not too bad. Page tips in rear lower corner bent outwards somewhat. A neat look at standards development for the radio in the early 1930's. Available for $7.

"Elements of Radio Communication" by Morecroft, John H., John Wiley & Sons, 1929. The 269 page hardbound book is in good+ condition. There is a previous owners name inside the front and rear covers, and light pencil marks/notes on many of the pages. Dust jacket has extensive tape reinforcement along the edges. A nice early text on the radio. Available for $10.

"Principles and Practice of Radio Servicing" by Hicks, H.J., McGraw-Hill, 1943. Second edition. The 391 page hardbound book is in very good condition, clean with no page tears or pen marks. A nice early text on radio repair. Available for $12.

"Radio Propagation Handbook" by Saveskie, Peter N., New York, NY, U.S.A. : T A B Books, 1980. 1st Edition. Red boards. The 499 page hardbound book is in very good condition. There are address labels from the previous owner inside the front and rear covers, and an embossed property stamp on the title page, otherwise very nice. Available for $20.

If interested in any of the above, please email to "Oldbooks78@aol.com" to reserve. Thanks, and best regards.

Dave

19. Anothe Parts Deal

Source record: 21352

I have ended up with several thousand PN2222A NPN's and PN3906 PNP's transistors in TO92 format.

These are new "old stock" and they came from Micro Electronics. Nice long leads too.

These are BULK transistors, so they are blank. They do not have the part number on them.

$2.75 per hundred, plus shipping.

In the US, I will ship via USPS. 100 of these in a bubble pack mailing envelope with 1st Class postage will run $1.30, I think I can put 200 in the mailer for the same postage.

If you are interested in these, let me know.

NO PAYPAL on this one.

Brian -

Are the 2N2222A transistors metal or plastic case?

Good then build a few.

Seriously, I've built 6 of these of various types, frequencies and
bandwidths. My feeling is filters using crystals between 6 and 22 mhz
seem to work best for SSB filters and the lower freqs do well for
narrower CW filters. The best one I've done was a 6 crystal filter
with a 2.4 at 6db bandwidth and good shape down to -60db.

Success is easy to achieve if you measure the crystals and apply the
math carefully. You need to know the characteristics of crystals your
using and also assure they are of the same frequency and quality.
Usually I buy 10 or 20 at very low price and hand sort them.

I have a choice of two op-amps for an audio application.

Which of the two, TL064 or TLC274 would generate the lowest internal noise in a 300 - 3000 Hz audio application.

Thanks

MikeN

I have a box full of about 400 8.3886 mhz rocks I got for about
$10 on ebay. I hope to make a filter or two out of them for ssb.
They are the larger hc6u type.

Dan's Small Parts for a RX I am building. They look quite good on my SNA.
Anxious to finish the N2PK VNA so I can see group delay.
The AM filter required toroidal in/out transformers to reduce the in/out Z
down to 200 OHms of the 2 narrower filters. I characterized the crystals on
an HP network analyzer and used W7ZOI's math.

It's in the product description from TI, the TLC274 is 25nV/rtHz, the TL064 is 42nV/rtHz, not ultra-low by the standard of the AD797.

Source record: 21362

Anyone have some unused solder connect .085" (RG-405) SMA plugs that they would like to swap for
Belden #9307 Conformable coax cable? I believe this is identical or substantially identical to #1671A. Label says:

Conformable (TM) 50 ohm Coax Cable
24 AWG (.21 sq mm) silver plated Cu covered steel
.022 (.56 mm) TFE Teflon Dielectric
Cu-Tin composite shield 100% coverage
.085" O.D.

Proposed exchange rate about 2' of coax per SMA connector, subject to negotiation.

Brad

Sounds like a good story, except:

Why would he need to take the mic apart when he could just use the push
to talk switch?

If the "radio broke", how was he able to transmit at all?

If what really broke was the mic or the modulation section of the only
comm radio on board, transmitting a long carrier on a regular basis
would get the attention of ATC personnel and resulted in a call to the
aircraft.

If he was an instructor, or a pilot at all, he should know the procedures for communications failure as described in FARs 91.126, 91.127, and 91.129, none of which call for using morse code.

FAR 91.185 wouldn't apply since he couldn't be flying IFR with just one radio.

Good point. But nowadays, why not call the tower's published telephone number on your cell phone? In the early '70s an acquaintance used 2M autopatch to get landing clearance for the USAF C-130 Herculese he was flying when its radios died - thought the Barksdale AFB tower folks were mighty surprised to get that call long before the days of cell phones...

Get your innovation noticed! Submit it to Wireless Innovation Contest.

If you've created something that's really making a difference, then we want to hear about it. And, more importantly, we want to tell the World about it.

2005 Wireless Innovation Contest takes place in Vancouver, BC Canada. The 2005 Wireless Innovation Contest is out to prove how wireless is changing the world. It could be a successful product, an enterprise solution that saved your customer thousands of dollars, a government solution that helped save lives or enhanced education or an entertainment solution that has made the world a lot more fun.

Nokia, Telus Mobility and other Industry Partners throw Support Behind the Contest this year. A panel of industry leaders will judge each entry and decide on a winner and runner-ups. Winners of WIC 2005 are rewarded with targeted exposure in media and at trade shows, inclusion in a specialcase study publication and a one-hour mentor session with the panel of judges.

More information is available at www.winbc.org/contest

36. Making our own valves (Tubes for the Non-English-Speaking Yanks)

As time passes, valves of the sort and size that we use in our TX's
are becoming increasingly rare and expensive.

There is nearly a century of folklore and industrial craft in producing
valves and overcoming problems thereto, and it seems to me that now is the
time to gather together this expertise before all the associated craftsmen
and industrialists go to the grave and their knowledge becomes lost
forever.

Armed with such a body of knowledge, could we Radio Hams, as a body of
technically-motivated and technically-inspired aficionados, then consider
manufacturing our own?

Is it not, after all, our pride in such technical activity that sets us
apart from
the CBer who buys all his gear from a shop (and even sends it back their
if ever it needs repair)?

Well - there could be a market in this - though would the 'tooling up'
be more of an outlay than you would reap back?

> Is it not, after all, our pride in such technical activity that sets us
> apart from
> the CBer who buys all his gear from a shop (and even sends it back their

Was there any need to mention 'CBer' in this posting? Totally uneeded
and unrelated.

Why stop there? Why not make your own capacitors, resistors, crystals etc. If you replace the valves (tubes) in your old TX with your shiny new "home made" ones, what happens when some other component fails? Do you pop down to your local electronics supplier (shop)and buy one of the shelf, Just like a CBer? Or will you make your own?

Anyway as far as I can see you couldn't make a "bloody mess" without buggering it up!

A *Real Radio Ham* would make his own Universe.

Cheers,

Micky

Maybe you would like to buy my wire. I have one spool of wire marked
"Grid Wire" and another
of Tungsten (filament wire ?). I picked them up from surplus and don't
know who threw them out.

Don't you have the interlect to do anything original? All you seem to do is
follow or criticise better men, neither of which you do very well.

Or is this your latest money making scheme?

(After seeing the financial status of your company from HULLY's link I see
you need one.)

Tell us, did your foray into AI not make you heaps of money?

Quote made by you on 1998/11/19

"My main side-interest is to get an understanding of consciousness
(Iwant to make heaps of money in AI & robotics!) mainly through
introspection; it is with some shock that I realise for how long
this has been going on; my philosophy notebook dates back 12 years."

That study is now 18 years advanced! (Even longer than you've studied DSP!)

Any return yet? No?

Maybe this introspection is the problem. Had you thought of studying someone
with some real intelligence?

I have a late 70s Yaesu FRG-7700 that has a partially working display IC that won't blank center segments. I'd like to find a new or used one or a buy a dead Yaesu or Kenwood R-1000 or other equipment that uses one. It's a 40 pin IC made by OKI stamped MSM5524RS. I've seen the one for auction on Yahoo in Singapore but it's too pricey for this radio because it still has other problems. Any tips or leads appreciated.
tnx

Hank,

Call 4 Star Electronics at 949.240.8500 or you can use a search engine with the IC number only and look for this company. They have a quote page you fill out.

This occured long before cell phones and perhaps even before the common
availability of HT's. He has been a ham for about 50 years and was a pilot
instructor around 30 years ago. Now he develops software and is part owner
of a utility trailer mfr. If you doubt his truth (which I don't, he is one
of the most honest people I know) contact W5WQN and ask him about it.

It was the ptt on the mic that broke, so as another noted, he couldn't just
key down on the mic and get the towers attention.

As for following proper rules, this is Texas, we tend to do what is needed,
not what some drone in Washington comes up with as rules.
thanks, John.

"Suitable for EME" and "Microwave Modules 432/28" don't really belong in the same sentence. It's a very old design, with poor spectral purity and very audible drift - quite literally, you could pick one out from half-a-million miles away!

Something like the Down East Microwave 432-28 model, ready-built or kit, would be much better.

Source record: 21399

John W. suggested an AD797 as a standard of comparison for voltage noise, which is fine, but for lowest noise figure, you need to know the source impedance that will be driving the circuit, and you need to be careful about part values in the rest of the circuit as well. Suggest you have a look at some other amps...there are so many good ones available these days. Since you mentioned two quad op amps, I assume you want to use a quad, and not singles like the AD797. TLC074 might be a better choice than either of your suggestions. There are other factors you may not have considered. The TLC274 has very limited slew rate for audio applications, and can only put out a bit over a volt p-p at 3kHz, for example. Is distortion an issue? If so, you at least should pick an amp with adequate slew rate.

If you'd like to optimize the choice of amplifier a bit better, and can pick from a wider range than just the two you mentioned, perhaps you could tell us more about the application and what other constraints there may be.

Cheers,
Tom

Even if true, rather than being an example of "morse code saves the day",
it is an example of stupidity.

Contrary to what most of the non-flying public may think, loss of
communications in the air is a non-event and not a life or death situation.

If you lose communications at a towered airport, all you have lost is the
ability to get traffic information from the tower.

Essentially what you are supposed to do is carefully enter the pattern
being extra vigilant for other aircraft and watch the tower for light
gun signals.

The pilot's attention needs to be outside the aircraft looking for other
aircraft, not screwing around playing with microphone wires.

Actions as described might be part of the reason this person "used to be"
an instructor.

The "comms failure" procedure is taught to student pilots (at least here in .au)
AND PRACTICED prior to their PPL. You enter via the normal entry point and
route, obviously maintaining separation. The tower intially will challenge you,
then on no response will request an acknowledgement that you can read THEIR
transmissions. If you can read them, they simply direct you and keep other
aircraft advised. In the absence of an ACK, it's the light system - and from
the challenge point onwards they alert other aircraft to the situation, so there
is minimal hazard.

Rule of thumb here is 90% outside, 10% on instruments for VFR

It is basically the same in the US.

So far I've had three comm failures in flight in rental aircraft, none of
which caused the slightest sweat.

In 1975, I worked for a marine radio company called Konel.
I worked on their first synthesized radio, which I inherited
from another designer. The original design had a VCO that
was quite microphonic. We didn't even bother with beeswax,
we potted itin Red Glyptol. Even that wasn't good enough
for two reasons. The speaker was in the same box and the
sailors would turn it up so you could hear the radio over
the engine noise. Also, the 10,000 HP engines on tug boats
produced a lot of vibration which got into the VCO.
I designed a VCO with an inductor printed on the PC board,
and that did the trick. A few months later, Konel went
out of business and few if any radios were produced.

Even British WW2 equipment used beeswax, although the result wasn't
always so good, or perhaps not only English equipment since it was
mentioned in CQ, see http://home.online.no/~la8ak/93a.htm

cable lacing... a lost art.

Is there anything that a laced cable-bundle does better than a
tie-wrapped cable-bundle?

Feed through a round tube.

Look good.

Lacing is still alive and well, it's used for many harnesses in
aerospace equipment, although tie-wrap is being used as well.

I don't know about "does better" but it sure looks good.

My background is in aviation maintenance and I laced the wires in a street rod years ago; very labor intensive but I got some comments on it from those had never seen it done. IMO it looks better in bundles where the wire is all the same color, the various colored wire commonly used in automotive applications doesn't look as good laced.

Lacing might contribute a little extra strength in the long direction.

Plus, as others have noted, it looks better.

Lacing (if it really a nylon laced tube) protects wires from
failure due to constant vibration (ie automotive). Also the
lacing can hold cable together over long distances without
compressing insulation too tightly at the nylon ty wrapped.
Missing information is the environment for that cable. Looks
really have little to due with why things are done.
Furthermore, sometimes a better looking (cleaner) installation
can make things electrically worse.

Hi i just got an old pager PA and I`m planning to convert it for 2m use. For this project I need to put in two relays for bypassing the amp while receiving. Can anyone recommend the relays?
I`m also thinking of putting in a relay to take the power of the PA module while receiving to protect the transistors.

Any hints and kinks will help me allot.

Geir

No, it isn't a PMT.

The 1P25 was the first commercial infrared image converter, now commonly called a "night vision" tube. Infrared energy is focused onto the photocathode at the large end of the tube, and a green image appears on a phosphor screen at the small end. These were used in "snooperscopes" and "sniperscopes" during WW2.

Firing it up requires about 5,000 V at a very low current. A resistive voltage divider sets the potentials for focusing, etc. The tube was declassified shortly after the war, and a good overview of it's operation was published in the Sept. 1946 issue of "Electronics". If you can't get a copy, email me and I can scan it for you.

That is true... *if* both are done correctly.

However, the usual poor job of lacing will have few if any
negative effects, while a poor job of using tie-wraps can
1) put crimps in the cables, 2) literally break wires, and
3) leave some very sharp edges that can slice up hands that
handle the bundle years into the future.

Hence, if the craftperson knows what they're doing... lacing is
pretty and tie-wrapping is easy. If they don't really know the
difference, lacing is safer.

Just picked up (actually it too heavy to just pick up)
one of these old boat anchors. The cost was less tnan
a large coffee so I guess the fellow Ham wanted to move
it out of his basement!!
It makes a nice squiggly line when plugged in but without
a manual, I may have to turn it into a back doorstep.

No hits back on a "google' on this model.
Anyone familiar with this unit??

George- Nova Scotia

Ty wrap, for example, a coaxial cable. Now wire's
characteristic impedance is changed where ty wrap pressure has
changed dimensions of cable.

Lenof21 wrote:

> All licensees are perfectly legal to continue operating in their grace
> period.

Nope. Wrong. You are mistaken. Once an amateur's license expires,
he or she *cannot* legally operate until the is renewed.

To quote FCC rules:

"97.21(b) A person whose amateur station license grant has expired
may apply to the FCC for renewal of the license grant for another term
during a 2 year filing grace period. The application must be received
t the address specified above prior to the end of the grace period.
Unless and until the license grant is renewed, no privileges in this Part
are conferred."

Last sentence says it all: "Unless and until the license grant is renewed,
no privileges in this Part are conferred."

This isn't some fine point of the rules that's subject to interpretation.
FCC amateur licenses have 10 year terms, and if a license is allowed
to expire, the licensee *cannot* legally operate until the license is renewed.

Do you agree or disagree, Len?

> There is no necessity (nor sense) to eliminate those in the
> grace period from those in the normal 10-year license period from
> any class totals.

Sure there is - their licenses are expired and they cannot operate.

If you want to include expired-but-in-the-grace-period licensees in
the totals, go right ahead. But be sure to indicate that you are doing
so, unless *you* want to "massage" the numbers.

The numbers I post twice each month are the totals of *unexpired*
licenses held by *individuals*. That's clear (to people who can
understand plain English) in every one of my post of license totals.
Nothing "massaged" about them.

> To repeat, the allegation that there is a "big drop" in Technician
> Class numbers is WRONG. Raw data doesn't show that.

What "raw data" have you examined, Len?

"hamdata.com" isn't "raw data".

Have you downloaded the FCC database? Processed it yourself?
Or do you simply take the numbers from a trusted website, same as
I do?

>Implying that the allegation still exists is merely compounding the wrongness.

Who made such an allegation, Len?

The sum of *unexpired* Technicians and Technician Pluses *has* declined since
May of 2000.

That is the answer indeed.

Applying tie wraps on a coaxial cable with a copper braid - even without exaggerating the pressure - precisely every 20 cm or so over tens of meters makes great filters.

I suppose lacing allows a milder treatment for RF cables.

Corretomundo..... the "grace" period is only for renewing to save you from having to retest for that class of license.
While it is expired - as in past the expiration date, you are NOT permitted to operate. The difference now is - where before you had to wait for the license to arrive in the mail, now you do not. Once you apply for renewal online and see it in the FCC database as having been renewed, then you can resume operations prior to receiving your new license in the mail.

In the case of temprature extremes (outdoor applications, direct UV exposure or vacuum tube chassis), I belive a laced bundle will outlive a tie strapped bundle. Also more economical - have you seen the prices of zip-ties that can handle the environmental extremes of good ol' lacing? EEEK!

Indeed there is a difference, notably in the aviation world.

Look inside the avionics bay of a commercial jet sometime. Come to
think of it, look at the innards of any piece of older avionics gear
that uses point-to-point wiring instead of, or in addition to, a printed
circuit backplane. What you'll see is the absence of tie-wraps, and an
abundance of laced cable harnesses.

I used to work at Boeing, and I had some friends in the Wire
Design group. I asked about this very question once. I was told that
tie-wraps are not favored for two reasons.

(1) If the tension on the tie-wrap is too high, it can crush
fragile coaxial cables.

(2) It's much easier to damage wire insulation under tie-wraps in
a high-vibration environment. Lacing twine is nowhere near as sharp
along its edges, and thus does not nick or cut said insulation.

Keep the peace(es).

>
> Thanks...

You can use half of your bridge with this transformer to produce
something like 22 volts DC at the filter cap. Connect each end ot the
secondary to one of the AC inputs ot the bridge and connect the cap
and load between one of the DC connections of the bridge and the
center tap. If you use the + terminal of the bridge, it will be the
positive output. If you use the - terminal of the bridge, the center
tap will be the positive output.

The bridges will handle a bit more current than they are rated for,
because only two of the 4 rectifiers will be getting hot. They will
certainly need a heat sink for anything like 20 amperes out, though.

After you get that working and running a couple 12 volt headlights in
series (at least), you can start thinking about how to regulate this
down to 12 volts.

>is finally finished and available for download at -
>
> http://www.designinganalogchips.com/

Thank you for the link and advisory!

Camenzind's book is EXCELLENT in describing the elementary
semiconductor junctions and how/why they came to be. The
capsule history of the transistor and integrated circuits, along
with its movers and shakers who made it all possible is well worth
the time of downloading something bigger than 20 MB (the
manuscript is 280+ pages long). [set it up, go do some other
things, come back in an hour if you have dial-up in order to see if
it all came down] Note: Hans' comments on some of the personalities
involved in semiconductors favors Silicon Valley, but that's under-
standable considering his long involvement there.

The majority of the text is for actual IC design but that does tie in
with detailed circuit designing done with packages as well. I thought
it an excellent bridge between the insides and outsides of ICs. Gives
a better "feel" for lots of the rules and specs of ICs when connecting to
them and trying to make things work.

Despite an "easy" writing style and minimal math, it ain't a "Dummies"
kind of book. Those who've just learned to handle Ohm's Law should
wait a few years before tackling it.

I think the advantage of lacing here is that the loops around the bundle
are held in place along the length of the bundle. With tie wraps, more
pressure is needed to keep them from slipping over time.

> I used to work at Boeing, and I had some friends in the Wire
>Design group. I asked about this very question once. I was told that
>tie-wraps are not favored for two reasons.

Ahem...Boeing is not necessarily a good source for wire bundles
that are "safe." See the NTSB report on the air liner that blew up
just outside of NYC over the bay...especially the part investigating
wire bundles going through a fuselange gas tank.

On the other hand, military avionics has used waxed nylon cord
(usually dyed black) and made under a MIL SPEC since the 1950s,
prinicipally because it was a neat, cheap way to bundle up wires
that were not otherwise clamped together.

Lots of folks use tie-wraps (trade name of one is "Ty-rap") but
invariably use sizes way too big for the purpose. There's a MIL
SPEC for that, too, if anyone bothers to look it up.

I bought a package of 100 Ty-Raps at DoItCenters couple months ago
to hold up an outside planter's drip irrigation tubing to an aluminum
awning. Tubing is very soft, about 1/4" diameter. 8-inch tie wraps,

standard white nylon material. No problem. No stoppages, no damages, but didn't try to put a full arm's strength into completing the tie. :-).

> (1) If the tension on the tie-wrap is too high, it can crush
>fragile coaxial cables.

Yeah, right. :-) Crushing RG-8? :-) How about semi-rigid SMA coax? :-)

I can't see, nor haven't seen anyplace that either tie-wraps or laces up coax cable of any size/type. Clamping with cushioned clamps, yes.

> (2) It's much easier to damage wire insulation under tie-wraps in
>a high-vibration environment. Lacing twine is nowhere near as sharp
>along its edges, and thus does not nick or cut said insulation.

Not necessarily true. Any tied/laced bundle of wires can be damaged by doing it at the wrong place with hi-g shock/vibration. I've seen improper lacing damage wire bundles (nylon-jacketed PVC, MIL SPEC for aircraft) just by the wrong operator's technique. I've seen tie-wrap bundles survive horrible hi-g vibration (in excess of 0.06 inch DA)...and some that failed a single 10g shock drop.

Nicely done lacing can be a neato show-job that could pass QA with flying colors. That's its main attraction: Looking good.

If there's to be some reasonably guaranteed, actual protection, then WEAVE lacing cord all around the bundle and make it super-neat looking. Distribution of tension quite even over all wires. Can cost a small fortune for a weaving machine plus all the spindles of lacing cord, though. Great way to make cable break-outs! :-)

Waxed nylon lacing cord is great for spot-tying small Teflon-insulated wire bundles. A 25 W iron can do the cut-offs and also melt the edges in the same operation.

Electrons, fields and waves don't always go along with human esthetic tastes of "neatness." :-)

> (usually dyed black) and made under a MIL SPEC since the 1950s,
> prinicipally because it was a neat, cheap way to bundle up wires
> that were not otherwise clamped together.

Here's my take on this (I laced a lot of wires
in the 1950s).

Wiring *harnesses* were made to facilitate
interconnection in equipment. Boards of
plywood with a drawing of the harness glued
on were the pattern, and finishing nails used
as guides for the wires. Wires were laid into
this guide according to a printed list. These
wires were usually pre-stripped and tinned.
Then the wires were soldered to connectors
when appropriate, and finally it was laced up.
This served both to constrain the wires, and
to make the harness easier to handle while
it was installed in the equipment. The stitches
or knots had to be done precisely according
to a MIL-Spec. It wasn't a lot of fun, and I
can remember rush jobs where everybody
from the lowest technician (me) to the engineering
manager worked long hours to make those
harnesses! Sure looked nice when it was done!

BTW, we only used white waxed nylon.

Biggest advantage is you don't get cut by poorly trimmed tie wraps!

It weighs less, costs less, requires less equipment to install .
I've never heard of anyone slicing their hand open on lacing but I've
seen some serious lacerations from the cut-ends of tie-wrap.

If you've never done it, give it a try. Even if you don't use it,
it's a handy skill to have in your warbag.

Looks like a sausage wrapped in string. The string may be waxed string (old
style) or small diameter plastic tubing.

RS Components (rswww.com) have it under part number 554-080
and describe it as: "A strong and flexible rayon-cored PVC
string for all ‘cable-forming’ and similar applications.
Dia. 0·75 mm. Breaking strain 4·5 kg (10 lb).
Colour: Black."

The start and finish knots, as well as the intermediate
ones, are very specific and designed so that the cord will
not work loose or the knots move on the cable assembly.

Laced "Commercial" wiring looms are normally assembled on a
make-up board which has the position of every knot clearly
defined along the length of the loom - so each wiring loom
turns out identical.

Once you are taught how to lace, you don't forget. Probably
something to do with the instructor cutting the whole lacing
off the loom for a single knot incorrectly positioned,
tensioned or done - leaving you to do the whole job again,
and again and again.

It didn't used to pay to be "the" female apprentice as
females are supposed to have nimbler fingers, a greater
attention to detail and more patience for doing mundane
repetitive work. So, whereas the guys could get away with a
half-assed job, I got to see the same loom time and time
again... Or it could just be I missed out that bit of the
genes...

The ARRL published a book about spread spectrum quite a while ago. The Brittish magazine "Electronics & Wireless World" published a 2 part article at least 5 years ago.

It is one of the Magnetic 8172 on your web.
The plan is to take out the circulator and place the TX relay there instead.
The LP-filter I`ll probably leave or mabe replace it with a bandpass for 2m.

No one has mentioned that cable mining is much safer and easier with laced
cables and can be impossible with ty wrapped cables.

124. A proposal for the body of Hams that make up this NG.....

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-01-09 15:04:59 UTC
From: "Airy R. Bean" <me@privacy.net>
Message-ID: <34cvmdF42au28U1@individual.net>

.....is that we club together and conceive of a design
for an HF transceiver that could form the basis of the
station of any budding Radio Ham.

We wouldn't need any facilities other than were present in,
say, the KW2000 of 35 years ago (apart from greater than
200 kHz coverage on each band!)

None of the CBer's facilities such as scanners, memories,
CAT interfaces, CTCSS and the like are necessary.

I suggest that we consider a DSP approach for all the
baseband mod and demod, and then phasing techniques
for translating into the various bands.

A power output of 5W will be more than sufficient for
any self-respecting _REAL_ Radio Hams - it is only
CBers and CBers-Masquerading-As-Radio-Hams who
need to work with BBC levels of signal strength.

Such a project could be what we need to capture the
interest of newcomers who would not then be sidetracked
into the CB-like purchasing of brand-new rigs from the
shelves of emporia, and, having, constructed their own
rigs, would feel competent to maintain those rigs, unlike
those who send them back to the emporia and thus show
themselves as closet CBers.

We _COULD_ take a lead in this NG!

Indeed, not a bad idea at all.

However, what is to be gained by re-inventing a (in radio terms) stone age
design?

Thinks like computer control provide added challenge and attraction to the
idea, why dismiss them? They could always be add-ons. DSP. Oh dear. I
assume this phasing technique relies on Big K.

Or maybe he just meant mixing, an existing technique not needing DSP.

BOY! These 'How-To' websites certainly bring back memories. These are the methods, procedures, & materials we used when I hired on with Western Electric in the early 50s. In those days we used tons of #6 & #12 cord for securing gazillions of feet of telephone cables inside the telephone company switching central offices. We also got lots of blisters & calluses while making the cabling look neat & secure. Cable mining? YUK!

Thanks!

Ron

I've little doubt that is his ploy. However, I lean toward being of an
overly forgiving nature and, if he can behave, maybe some good will come of
it and he will learn something.

At worst we can go back though Google and refer him to previous answers.

M3OSN continues to exhibit a negative and destructive
maladjusted personality and demonstrates well why
anybody who holds, or who has ever held, a licence
issued under the gangrenous degeneration that is the
M3/CB Fools' Licence scheme will never make it into
the ranks of _REAL_ Radio Hams.

What is to be gained by designing a radio that is, or should
be, reproducible with ease by newcomers? Nothing if you're
a defeatist SFB Jonah such as Mr.Reay presents below, but everything if
you have the makings of being a _REAL_ Radio Ham!

Stone-age design? What a silly-billy is Mr.Reay! No doubt
by that childish sneer he reveals himself to be one of the
CB types who buys his radios off-the-shelf! What a bad
example he presents to any prospective newcomers!

Once again Mr.Reay demonstrates why he will always be
no more than an SFB CBer and never a _REAL_ Radio Ham!
(Newcomers! Do you wish to be a sneering failure such as
Mr.Reay presents, or do you wish to join the Radio Hams?)

(I see that the spikeful Old Mother-Hen Nugatory RVMJ-Binary Era
is still demonstrating her paranoid obsessive ways.)

As to Mr.Reay's rather silly and snide comments, I always behave
in a respectable manner in this NG. It is Mr.Reay, with his obsession
of sheep-shagging who regularly resorts to rather silly and childish
outbursts; witness his two sneering contributions to this thread already!

Mr.Reay does have one useful redeeming feature; he does illustrate
to a "T" why anybody who holds, or who has ever held, a licence
issued under the gangrenous degeneration that is the M3/CB Fools'
Licence scheme will never make it into the ranks of _REAL_ Radio
hams and thus may yet serve to put off newcomers from making the
mistake of taking up such a licence.

Perhaps even Mr.Reay may learn something from this thread - how to
behave in a respectable manner more suited to an international
public forum than the infantile boastful manner that is his wont?

Hmm...perhaps it's just another turn of the ever-repeating cycle?

>At worst we can go back though Google and refer him to previous answers.

Afraid not - he doesn't follow urls. I don't know if this is from
unfamiliarity with usenet, or that he can't read a reference and
understand which parts were relevant to the discussion. And anyway, if
you start quoting him back at himself, he killfiles you. Allegedly.

Well some people are slow learners. In fact, I seem to recall one student of
DSP admitting he was just such a slow learner.

If he learns just one new thing every cycle, have we not a duty as radio
amateurs to try and assist him? OK, it maybe painful for us, he will be
ungrateful, it may seem like we are banging out heads against a brick wall,
but think of the challenge. We could succeed where Essex University failed!

Treat it as another challenge- something we can teach him.

I'm almost tempted to let him out of the killfile but I think I'll just
watch the follow ups for now. With a recalcitrant people it does no good to

give them too much rope early on.

From my past reading of this newsgroup, you've tabled this suggestion
to the various newsgroups before, and despite many viable suggestions
and offers of support, have done little with the responses.

(This is actually a copy and paste of the past posting isn't it old bean!)

Apart from wanting DSP, I can offer you the ideal radios all ready built
for the job - either the KW2000, the FT101 or the FT102! Why re-invent
the wheel?

> A power output of 5W will be more than sufficient for
> any self-respecting _REAL_ Radio Hams - it is only

Oh dear - a lot of us have already lost interest now due to this post
Masquerading-As-Leigitimate-But-Really-Is-Just-An-Excuse-To-Provoke-More-Comments.

If you want 5w with DSP - go for the Elecraft K2 which you can construct
in stages!!!

> Such a project could be what we need to capture the

Yes - an ideal road to go down but sadly somewhat restricted by the UK Foundation Licence that only allows the use of type-approved equipment - unless you propose you can gain type-approval for your design and eventual product that will probably cost a lot more than a purchased radio?!

(I note you use the term 'rig' rather than 'radio' which is the more _Gentlemanly_ way of traditionally talking about your equipment - surely the word 'rig' is a term used by a CB'er that you detest so much?)

Just my thoughts....nothing even like a provoke!

David.

The restriction isn't "type approved" transmitters- they can use commercial
equipment designed for the amateur market (eg Yaesu et al) and those made
from commercial kits. The words "type approved" etc do not feature.

Plus, of course, as the newcomers progress there is the option of totally
home brew designs (ie not from kits). As a group, we should be encouraging
M3s to progress so let us not get bogged down with this.

More bullshitting, side-stepping and downright lying.

If the rigs are home designed and constructed then they are of
a type that is not approved.

Mr.Reay proves to be a silly-billy once again.

As a group, we should definitely _NOT_ be encouraging those who
have a licence issued under the gangrenous degeneration that
is the M3/CB Fools' Licence scheme one iota! Such people
are not Radio Hams by any stretch of the imagination.

Perhaps uk.rec.radio.cb, as a group, would be more appropriate?

Thanks for clearing this up Brian.

I for one support the M3 licence scheme and the progress up the licence
classes to gain more skills and aid self-development.

David.

Which is always the problem in community-based projects - defining what
the actual goals are :-)
There is a definite place for "stone age" design in teaching the basics
(simple single band sets, etc.), but I would personally like to put
together something more cutting edge.

>
>Thinks like computer control provide added challenge and attraction to the
>idea, why dismiss them? They could always be add-ons.

That would be my ideal for a project like this - the design split into
discrete modules, which can be mixed & matched to provide the facilities
wanted. This would also help out in getting it going, as you can split
the effort into teams with their own competencies (e.g. a PSU team, a
display team, a PA team, etc.), who all know what the interface to their
module has to be in order to work with the rest of the kit, but other
than that have free reign in design.

Manage it with a sourceforge-style website (where schematics, processor
code etc. can be checked into a version control system), and you'd have
a chance of pulling it together even with geographically separated
teams.

You'd end up with something like an open-hardware K2 - something I'd
really like to build once I get some free time (currently scheduled for
May 2023).

It is quite likely that a reasonably "modern" radio with bells &
whistles would be more expensive than a rice box. Still, people build
the K2 (which on paper at least costs more and does less than a
Yaekencom box), because at the end of the day this is a hobby, and you
do it as an enjoyable way of passing time & learning something rather
than as a commercial endeavour (why do people spend years building a
model boat out of matchsticks when they could buy a far more functional
radio controlled one from the local toyshop for ï¿½20?).

>The restriction isn't "type approved" transmitters- they can use commercial

So I guess that whilst a project like this wouldn't be acceptable for an
M3, if a company released a kit version of the project then it would be
OK (as it would be commercial then)?

>What is cable mining?

New cables are laid into cable racks on top of old cables, and
the old ones that are no longer used are just cut off where they
enter the cable rack and left in place. Eventually, of course,
the cable rack fills up with old unused cable.

So every decade or so some poor smucks get the job of removing
all old cables. And that... is cable mining.

It isn't fun and it isn't exciting (but if you get the cable it
might be profitable though).

And if any of the cable was put in with tie-wraps, you also get
your hands shredded from the sharp edges where the tie wraps
were cut off. That is bad enough if a proper tool is used, and
far worse if some dingbat has used snips to cut them.

Spiral Wrap is pretty nice and robust but when it comes to
fault-finding broken wires etc it can be a bitch.
Have a look at this :

http://www.geocities.com/svxdc/AI-pics/254-11a-HarnAdapWrap.jpg

I find this better for dirty/oily environments or where there's a
chance of vibration. The the harnes is easly "moulded" to fit intricate
contours.

I'm not proposing anything like that. I don't know
anything about the K2.

You seem to have missed the point somewhat, if your
thoughts go straight to what you can buy off the shelf.

I don't follow URL's from Usenet - it is a bad debating style
to send your correspondents off to do reading. if you have
something of value to say, then please say it yourself.

Well - the K2 is an American produced radio that is exactly what you are proposing. It is a QRP radio that is very small and compact that can be constructed in stages then tested and used. You then add to it as you go along - this teaching yourself construction and study the design idea.

> You seem to have missed the point somewhat, if your
> thoughts go straight to what you can buy off the shelf.

Yes - but this is a kit not obtainable off the shelf.

> I don't follow URL's from Usenet - it is a bad debating style
> to send your correspondents off to do reading. if you have
> something of value to say, then please say it yourself.

But - search do search for the Elekraft K2 - you'll be pleased, I hope, that is teaches everything you stand for - self training, construction and the development of _REAL_ skills.

David.

Are you mixing things together here?

There are full wave bridges that use a ct transformer and half wave bridges
that use non-ct transformers.

I know of no distiction between bridge rectifiers and full wave rectifiers
other than there can be full wave or half wave rectifiers and there is
usually a disctinction between encapsulated rectifier bridges and ones built
of discrete diodes and resisters.

After running a 32v ct transformer thru a full wave bridge you are going to
have way too much voltage for regulating down to 12v unless you enjoy the
extra heat.

Sounds like you intend to make a linear power supply, what sort of regulator
and pass transitors do you have in mind?
thanks, John.

>Geir

I might have used a smaller dpdt pcb relay from LA3VW which type is
tested by LA6LCA and LA8OJ, but don't know about the availability and
type, and it is some precautions to make to make it operate properly.
The easiest is always to use PIN diode, the Unitrode UM9401 is a very
easy choice (for the series diode), and the dealer is service minded,
at least they were when I bought some. Demanded 50, but they only had
25, and I later sold most of them to friends around, hi
This type of diode may be used to at least 1kW according to SM5BSZ,
but it is a quite complex switch design to do it, normally they are
good enough for more than 100W. The smaller diode could be 2x BA182 or
2x BA282 or something better in anti-parallel. I prefer the anti-
parallel configuration even if I use some current through the diodes
during transmit

It does use the transformer as-designed -- it just doesn't use all of
the bridge rectifier. This is what you're trying to do:

It's one of the very early 3 series Tek vertical amp plugins for the
560 series of scopes. You mentioned that your scope is a 568, but
which time base plugin does it have?

I like the 560 scopes, but the max bandwidth is only 10 MHz. For the
3A72, the bandwidth is only 650 kHz. The 3A1 and 3A6 will give you the
full 10 MHz bandwidth, and there are lots of specialty plugins which
are available out there for fairly cheap.

The 568 was made to work with a special digital unit which I believe
was supposed to readout times and voltages in digital form. I'm not
actually sure of what it was supposed to do, but it's mentioned in
Stan Griffith's Tek book. I've never worked with one.

Personally, I am most fond of the 564B, which is a later solid state
storage scope mainframe, but still limited to 10 MHz.

I'm always amazed at how often 10 MHz is plenty.

Not "off the shelf" product. I am very surprised that you are unaware of Elecraft (founded in 1998) by Wayne Burdick (N6KR) and Eric Swartz (WA6HHQ).
They are the design team dedicated to "hands-on" ham radio transceivers and accessories that can easily be built by amateurs.
> I don't follow URL's from Usenet - it is a bad debating style
> to send your correspondents off to do reading. if you have

I guess you do not read hobby print magazine or had a contact with an Elecraft user.
Elecraft (and its concept) of building and reparing your won equipment has been widely covered in amateur print magazines in Europe, Far East and US.

Debating is not the point and usenet is not the forum for true debate.
Compare your stated specifications and criteria to the Elecraft K2 design team's criteria and specs --- you shoudl discover that it meets the majority of your stated criteria.

169. HP 10544 OCXO

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-01-09 23:08:38 UTC
From: Arnd Gronenberg <arnd@gronenberg.com>
Message-ID: <crsdhnimb05$1@news.t-online.com>
Source record: 21202
Cross-posted to: sci.electronics.equipment,rec.radio.amateur.homebrew

Hi,

the HP 10544A OCXO driving my HP5328A counter failed due to a blown thermo fuse. The underlying problem was a broken Thermistor lead (unfortunately within the sealed hole) which caused the owen to run away (and blow the fuse). I already searched, but didn't find answers to the following questions. In order to find a suitable replacement thermistor, I would like to know:
- At what temperature does the OCXO nominally operate?
- What are the characteristics of the original thermistor used by HP? (my copy of the 10544 schematic lists the thermistor as "9.93K @80C 0637-0122", but it is difficult to distinguish "6" and "8")
- Which temperature specification is required for the thermo fuse?

Thanks in advance!

This also shows Gareth's view of Usenet - somewhere to stir up arguments
(sorry, "debates"), rather than somewhere to chat and exchange
information. "gb" posted an informative link, but Gareth refuses to
follow it and find something interesting because it doesn't suit his
agenda in starting an argument (sorry, "debate").

>power supply that makes use of a full wave rectifier? I've found quite
>a few for a bridge rectifier but I'm not really sure how to mod them
>to use a full wave rectifier.

Hi, Bridge rectifiers are full wave. Sounds like you want a full wave center tap arrangment. These are very common, surprised you could not find a schematic.
With a 32 volt center tapped xfmr, connect the center tap to common and attach 2 rather large diodes to the other two transformer leads, and common their anodes. You now have an unfiltered 22.6 volt full wave DC power supply. Xfmr CT is negative, and the diode anodes are positive.
To get to a 12 VDC regulated supply add sufficient filter capacitors, and regulator devices. A 12 volt 20 amp linear power supply requires heat sinks on the solid state devices. I use about 50,000mfd filtering on mine, and a 200 volt 50 amp darlington transistor, as the series pass transistor regulator. I used them because that is what I had on hand. The final design of your regulated supply will depend on a number of factors.

Arnd,
There is some really good info on the HP oscillator at
http://www.realhamradio.com/GPS_Frequency_Standard.htm, which describes uses
for the HP Z3801A GPS Receiver/Time Standard. The page at
http://www.realhamradio.com/z3801a-turning-point.htm gives you some really
great info on setting the crystal turning point temperature for the best
stability. This will help you to understand your questions about the
thermistor also. The oven isn't set to a standard temp, but to the best
temp that puts the crystal in the middle of its curve. The thermistor is
spec'ed at 100K @ 25C and 9.93K @ 80C. You'll have to shop around for a
suitable replacement, keeping in mind the physical size of the thermistor.
Mouser, Digikey, Allied, etc. are good sources of those. After replacement,
you'll have to go through the turning point calibration as described in the
above article. The thermistor is part of the oven mass assembly, and isn't
separately orderable from Agilent.

The thermal fuse isn't described in the documentation, just given a part
number. I don't have the manual for the 10544A, but I do have one for the
10811A/B oscillator, which is very similar.

Then you have the basis for a high current supply. You could get a slight increase in current capability by separating the two halves of the secondary, put a 4 diode bridge in each half and connect the outputs of those bridges in parallel, but the view is probably not worth the climb unless you really need every ampere this thing is capable of. And in that case you would want a switching regulator to convert volts to amperes, instead of a linear regulator. Lots more difficult.

Here is the data sheet for a control chip commonly used for high current linear regulators. The application notes (figure 5) give the general idea of what is required. You will have to come up with a bank of pass transistors (6 to 10 TIP36, perhaps and a big heat sink).

You have the rectifiers connected the wrong way to get a positive
output voltage. In half wave rectifiers, two diode CT full wave
rectifiers and in bridge rectifiers, the cathodes are always connected
to the _positive_ capacitor terminal.

Messing too much with microphone wires will make you a candidate for
the Darwin price due to the Controlled Flight into Terrain (CFIT)
syndrome.

A well known case is the L1011 crash in Florida killing 100, when the
crew were too occupied fixing the landing gear light problem and
forgot to fly the aircraft.

I wonder why Mr.Reay pours scorn on a proposal
which perhaps he himself ought to have come up
with bearing in mind his regular _BOASTING_ about how
important he perceives himself to be in the training
of newcomers?

Is it because he is tetchy (to use his own phrase) that he
didn't think of the idea first?

Perhaps, bearing in mind his recent boasts about share dealings,
he has shares in Waters And Stanton?

Either way, his rather silly and infantile sneering below does seem
to suggest that he is irrelevant to the future of _REAL_ Ham Radio;
and of no value to any scheme for beginners.

Whatever you say about your K2, it is a proprietary design,
and thus no different from the YaesKenIcom products, and
therefore is off-the-shelf

The essence of Ham Radio is that we produce and maintain
our own designs and are not beholden to any commercial
operation that has its sights set on the shekels.

I'm not interested in a comparison with commercial gear. The
idea is to design a transceiver that is easily reproducible by
beginners, and which is future-proofed by having the
interface between stages well-specified so that you could,
for example, substitute your own mixing stages.

Not "off the shelf" product. I am very surprised that you are unaware of
Elecraft (founded in 1998) by Wayne Burdick (N6KR) and Eric Swartz (WA6HHQ).
They are the design team dedicated to "hands-on" ham radio transceivers and
accessories that can easily be built by amateurs.

> I don't follow URL's from Usenet - it is a bad debating style
> to send your correspondents off to do reading. if you have
> something of value to say, then please say it yourself.
I guess you do not read hobby print magazine or had a contact with an
Elecraft user.
Elecraft (and its concept) of building and reparing your won equipment has
been widely covered in amateur print magazines in Europe, Far East and US.

Debating is not the point and usenet is not the forum for true debate.
Compare your stated specifications and criteria to the Elecraft K2 design
team's criteria and specs --- you shoudl discover that it meets the majority
of your stated criteria.

Top-posting is not the preferred option, unless you mean it is your
personal preference. You should be able to make the distinction
easily enough.

Good to hear from someone with VERY similar experiences,. I started in SxS, and of course the new guys always start on the cable crew. Tough job, so I soon learned how to get involved in 're-grade' of SxS. This got me out of the cabling, and into a softer job. I never got into X-Bar, so had no experience with 'troughs'. etc. A lot of PBX jobs, then hired on with the telco in about 1960, went to COE Engineering in 1966, and retired from toll equipment engineering in 1984. My calloused hands are now back to normal. I still have a half-roll of #6 cord which I've saved and I hate to use because then I'll be out of it <G>.

I'm now completely out of contact with those I worked with, so it is good to know that I'm not the only one still alive.

Thanks for the walk down Memory Lane.

Ron

Hi bill, I plan on experimenting with this on a very small scale (as far as power output goes) and would be monitoring the power density of the spectrum matrix at all times. It's just something I've always been very interested in.

Literally the last book I read that had anything to do with spread spectrum was the 1993 edition of the ARRL Handbook. I read enough of the basic theory to get me very interested, and it's been stewing in the back of my mind ever since. Recently I saw something the refired my interest once again in spread spectrum.

A Quote:

"Also, a 500mw spread spectrum device can easily have an effective range of over 20 miles. In 1994 I field tested a spread spectrum LPD/LPI handheld radio designed for downed pilots. The power would vary between one half milliwatt to one full watt based on the quality of a duplex link. With power levels below 25mw we could communicate clearly at a distance of 45 miles on the open ocean (from a life raft), and 15 miles in the dense woods of Maine. When the device was tested in a dense urban area, a range of 2500 to 8600 feet was obtained while keeping the power output *below* 15mw."

I've seen two publications on the web regarding spread spectrum:

The ARRL spread spectrum sourcebook at:
http://www.powells.com/cgi-bin/biblio?isbn=0872593177

and

TAPR's Spread Spectrum Update at:
http://www.tapr.org/tapr/html/Fpub.ss.html

Has anyone read either of these publications? I'm afraid I'm just a little rusty on the old algebra, trig and calculus. So a relatively math-free (not completely math-free, mind you) book would be appreciated.

As I understand it, the ARRL spread spectrum sourcebook is evidently a collection or articles put out by the ARRL/AMRAD on spread spectrum experiments. Would this be correct?

Like I said, I'm a beginner in this area, but usually learn quickly. Is there any such thing as, perhaps, a few "ready-made" kits or consumer devices that could be immediately utilized in exploring this fascinating field? This would be very nice indeed.

Dave

Thanks for the info, Caveat. Looks like I may have had run across one of your links in all my searching :)

There are many question I have regarding SS, but one that's bothering me in particular. Regarding the PN spreading sequence, these sequences obviously have to be aligned perfectly in both transmitter and receiver. Naturally they could be kept in sync if both circuits were initialized at the same time.

However, 3 things: 1) The circuits will not be initialized at the same time in 99% of most cases, as in the use of, say, a portable field radio. 2) If they were synchronized at the same time, well, no clock or oscillator is perfect. It would eventually drift. 3) As I understand it, there is no initial "handshake" signal at the beginning of transmission with the receiver to initialize/syncronize the PN sequences on both ends.

So in short, how do the PN sequences became and remain synchronized through time? Thanks.

Dave

> So in short, how do the PN sequences became and remain synchronized through time?
> Thanks.

Two ways that come to mind immediately:

1) The transmitter sending its state periodically, so that the
receiver can jam that into its spreading or hop control
registers and be instantly synchronized. No good for *secure*
comms, but great for insecure comms.

2) The transmitter using spreading or hop control based in some
way on (GPS) time, say by automatically loading new control
state periodically. The receiver would load the same control
state for that time period, and then could slew the clock
forward in time until it detected synchronization. This is a
variation on (1) which *is* good for secure comms.

Drift can be corrected by circuitry in the receiver, from the received
signal. If the link is via satellite, drift (and Doppler shift) *must*
be corrected in the receiver to maintain sync.

The alternate conclusion of course, might well be simply that your fame preceeds you Airhead. In truth, if you only read your own National magazine that you profess so much dislike for, you would find that they recently carried for some 20 months a construction article having every feature you have supposedly considered. Done by amateurs for amateurs and surpassing in most features, anything offered commercially at any price.

You're very good Airhead, you are the only one on any newsgroup that I subscribe to that can raise my blood pressure just by reading your byline. Fortunately, I am blessed with low blood pressure and can stand it, but to absolutely preclude any possible ill side effects, you are now entering my kill file zone. Too bad God made so many more horses asses than he did horses.

Hello everybody:

I am adjusting the LO hardware of my 2754P and there are some things that I
can not find or undestand:

After pressing shift 0 , loops calibration, overall system option the first
message is:

Connect a DVM on TP1058...etc (no problem)
(the meter shows 17mV)

Adjust frequency control
for a reading of 0.000 +/- 2mV

(problem WHICH FREQUENCY CONTROL?? OR POTENTIOMETER OR RESISTOR???)
The freuquency control board???

2.Connect a DVM on oint B of the controlled oscillator board and ground..
WHERE THE HECK IS POINT B AND WHERE IS THE CONTROLLED OSCILLATOR BOARD???

Thank you your help

Actually, Dr Reay said it was a good idea. He did point out a few flaws in your concept. As we have all done in the past.

You always react like this Gareth when one of your great ideas proves to be less than great. At least this failure isn't going to cost you your job.

Gareth has always been full of 'good ideas'. They just never seem to have
actually been implemented- be they radio, railway signalling, home made
hacksaws, or telecoms systems. He has always been so- way back to TMC days.

Something else you know nothing about. That list keeps growing Gareth. Have you thought of studying at all?

You have plenty of time on your hands. (Your posting times suggest you are not working at the moment.)

Standard practice for Gareth, has been so for years. Way back to the TMC
days. If he avoids research he can pretend it wasn't his fault when it goes
belly up.

Yes - but it isn't a propreitary design - it's simply been put together by a group of radio amateurs and there is scope within the kits to do your own modifications - making it way way different from the commercial far-eastern models.

> The essence of Ham Radio is that we produce and maintain

But, why not move with the times and include an element of computer control and computer based audio filtering rather then re-inventing the wheel.

As I've said before, apart from the DSP, I and other radio amateurs have radios here that match your criteria, so why should we bother?

David.

I had the ARRL spread spectrum sourcebook (before I sold it on eBay). It is
a bit a jumble of chapters:
A lot of legal and restrictive stuff (as SS originated in military comms and
can be used for covert and/or jam resistant communication)
Several articles on shift register sequences and coding gain.
Synchronisation
Some designs, but the digital parts are quite obsolete now.

Wim

Actually, if you care to look at Harold's website - www.W4ZCB.com, you'll see he is more than qualified to critise you old Bean - as he seems to have much more design and construction skills than you've dreamt of.

Then again, any common sense you have is often released against the porcelain I bet!

David.

The muppet demonstrates his silly attitude when challenged once more.

You know which magazine he means old Bean - except it's the official
organ of an organisation you despise so much.

Such pathetic and childish behaviour for a man in his 50s!

David.

The E&WW article used a Delay Locked Loop, 3 decoders, one fed with the
actual PN secquenc, one with a leading version and one with a lagging
version. The error signal was used to correct the PN clock.

What some military radios use is that the receiver hops much slower than the
transmitter before achieving synchronisation, so I will catch a signal at
some time.

>So in short, how do the PN sequences became and remain synchronized
>through time?
>Thanks.

The ones I'm familiar with - the Barker codes used in 802.11 DSS -
have the interesting characteristic that their auto-correlation is
extremely specific. That is: if you take two copies of the Barker
sequence, put 'em above one another, multiply them together (treating
the two states as 1 and -1 rather than 1 and 0) and then sum up the
products, you get a very high positive value (11, in the case of an
11-bit Barker code). If you invert one of the two before multiplying,
then you end up with a very large negative value (e.g. -11).

However, if you shift one of the sequences one or more bit positions
to either side (in a circular-shift fashion), and do the multiply-
and-add thing again, the final sum is very close to zero. In other
words, the correlation between a Barker code, and a time-shifted
version of that code, is very small.

So - in order to transmit using DSS, you take the incoming bits,
multiply (XOR) them with a Barker sequence of chips running at (e.g.)
11x the bit rate, and transmit. To receive, you take the incoming
(11x rate) pattern, and perform the "multiply and add" process against

the original Barker chip pattern at the full 11x rate. If nothing's being transmitted, and the input signal is simply noise, the correlation between the noise and the Barker pattern will be very low, and the sums coming out of the adder will be close to zero.

During a transmission, the sums from the correleator will also be close to 0 when the bits don't line up. Every 11th chip-time, though, when a complete bit's worth of chips from the receiver has entered the correlator, the sum will jump up to a high absolute value (+11 or -11 in the example case, if none of the chips were corrupted by noise). This sudden jump to a high absolute value tells you what the original data bit was (1 or 0) and can also create a synchronization pulse which you can use to discipline your receive oscillator.

The above description is crude, inexact, and may contain errors, but perhaps it gives the flavor of the method.

Maybe he never graduated? That could explain lots of things. Especially his
degree envy.

does specific-gravity of a conventional lead-acid cell, linearly
measure its AmpHour capacity?

If not, what exactly does it indicate with respect to the battery
user's needs?

It's proportional to % of charge. I doubt it is linear. See

Unions had nothing to do with it. I remember a job a friend did at an overhaul base on a Navy S2, (Grumman aircraft, if I remember right). Had a government inspector walking around watching the work. My bud had just spent most of two days lacing a long wire run inside the fuselage. Beady eyed little inspector got his eyes about 3 inches from the lacing, then took a tiny pair of sidecutters out of his shirt pocket and started cutting every last lace. My bud yelled at him, "What the @#&(are you doing?" Inspector says, "Wrong knot". Any of you old gray haired, (like me), A&P's remember the specified knot? I can still tie it blindfolded. If a particular aircraft had the wire runs to be laced in the standard practice manual for that aircraft, then you, by damn, laced them. Did more than my share on a few DC-6's.

231. Any good 13cm WideCoverage Receiver?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-01-11 02:22:02 UTC
From: Ultra Kiasu <ultrakiasu@hotmail.com>
Message-ID: <1105410122.863281.21050@c13g2000cwb.googlegroups.com>
Source record: 21114
Cross-posted to: alt.radio.scanner.uk, rec.radio.amateur.digital.misc, rec.radio.amateur.homebrew, rec.radio.scanner

I had scoured the net for cheaper 13cm (2.3-2.6 GHz) widecoverage
receiver with fine adjustable stepping LCD controller.

So far, had only found these 2 main suppliers at http://www.13cm.co.uk
and http://www.g1mfg.com which both is UK based.

G1MFG products look good but expensive, while 13cm's were cheap but
crude (required DIY connections).

Is there cheaper alternative, or better, ready-made (minimal
construction required) which LCD controller built-in?

I believe that since the main radio components are supplied by
Taiwanese company, Comtech, there should be more similar products
around the world, or at least, "clones".

Any good recommendation?

Thank you.

Regards,
Kevin

PS: Appreciate if you could email me a copy of your reply.

It is close enough to linear that some battery manufacturers provide
coefficients and/or graphs of SOC vs SG and temp.

It does of course require "calibration" to accomodate the actual acid/water
proportions at fill and any loss/replacement.

And you're talking about the specific gravity of just the liquid
electrolyte, of course, not the entire cell.

PN
>sequences on both ends.

While I can't give you a detailed example of how a portable field radio
(such
as the U.S. military's standard small-unit SINCGARS), there are a host of
already-working-for-a-long-time examples. One is the ordinary modem which
has both a "fast clocking" (almost like coarse acquisition) initial
synchronization that stabilizes the receiver decoder's internal bit rate,
then
an actual sync decoder from that to "line up" everthing.

With repetitive digital signals incoming, an ordinary modem borrows a
technique from magnetic data recording to set the decoding bit rate on the
transition of each pulse. Usually that is done at twice the bit rate to
grab
either transition. That can be a simple PLL with emphasis on the Phase,
but it can also be a simple R-C differentiator thing since the initial
timing
doesn't have to be precise. Once that is locked into place, the "fine
tuning"
for time synchronization can be done in several ways. One way is very
much like the old radar/transponder "coincidence detectors" which run a
pulse pair into a delay line and look for an AND (or coincidence) of the
input with the output, the pair's spacing equal to the delay line delay.
That
old "analogue" method was done in prehistoric times of tubes/valves and
useful in aviation radionavigation (IFF transponders, DME, all of which had

to coexist with unsynchronized pulse pairs from other interrogators).

A more modern way with digital logic is to use a multiple-stage Shift Register, clocking the S-R with the "coarse" bit rate achieved with the first data stream arrival. The S-R outputs can be Exclusive-ORed with the incoming signal and all the Ex-ORs ANDed to select the coincidence which was known for that particular system. The versatility of that is being able to
pick any sequence pattern of 1s and 0s desired to get that "time sync" (some prefer "framing" synchronization as a term) to get in step with the transmitter
signal. Once that framing lock has been achieved, it is not difficult to keep a
crystal oscillator phase-locked to the incoming bit rate (NTSC and PAL TV do that). The framing sync lock pattern could be 4 to 256 bits long, whatever
is system-desireable and there are no great demands on timing accuracy for that (fairly easy to work out if thinking in terms of time). With phase-
locking internal to the receiver, it aligns itself to the transmitter, no sweat.
There are no great demands on jitter specs to get initial bit rate sync or even to get framing sync; once the first sync is done, the system can fine tune itself to stay in timing.

A "framing sync" pattern is slightly wasteful overhead in that it can't carry
any data during its existance. From there on, there's all kinds of system variations possible depending on modulation rate, sampling times, time-multiplexing (if used), and all kinds of other things. Once a Tx-to-Rx sync has been achieved, the data portion can be tailored to fit...along with the internal stability necessary to limit the number of framing sync sendings to maintain a good lock. In the initial acquisition of a signal there's bound to
be some time wasted for the Rx to get in step with the Tx signal but that is quite short indeed despite a wide variation in such system architecture.

The ubiquitous "keyless" auto lock is an example of a very secure (through very long) digital bit pattern. Bandwidth isn't very high despite being UHF (for keyfob size packaging) but it does the whole works and determines the correct lock/unlock sequence (along with the convoluted decoding thing for security) very quick - does it before that one "squeep" of the horn
or speaker sounds.

Those of us who've worked with aircraft DME (Distance Measuring Equipment) will have seen the ability of simple pulse-pair "coincidence detection" work through a mass of "fruit" (pulse pairs from dozens of other aircraft) to pick out the time-delayed ground station response. No PLL needed there. The return signal is seen like right away on a scope, the scope synchronized to the DME interrogator signal. I've

forgotten the ARINC spec but it's like 200+ aircraft can be interrogating the ground station at the same time (ground station replies with a fixed 50 uSec time delay) and nobody interferes with anyone else.

In a modern digital example, the U.S. military SINCGARS field radios have an extremely tight spec temperature compensated (like its hard to believe how tight that is) internal crystal oscillator. The "Plugger" (old AN/PSN-11 GPS receiver) can attach to it and update the time to accuracy of the GPSS. Strangely enough, that isn't needed to get SINCGARS sets to work together as much as the precise time is needed to do networking, to get all the "hops" in sync (SINCGARS is a frequency-hopper hopping at about 10+ hops/second in addition to doing digitized voice and data). [see public data on AN/PRC-119 latest models from ITT Fort Wayne IN website] About a quarter million of the SINCGARS R/Ts have been produced since first operational around end of 1989. Extemely secure radio in the field and many can be working at the same time without interference to one another.

In conventional NTSC TV receivers, the color subcarrier sample of only 6 to 8 cycles of 3.58 MHz is sufficient to work the PLL in the receiver for holding on very tightly to that color burst signal. A crystal oscillator is used to insure minimal jitter and maximum phase hold for a single horizontal sweep time (NTSC is most unforgiving of phase errors). "Lost time" due to sending the color burst is only about 2 1/2 percent of a horizontal sweep duration. While that isn't an SS thing it shows that overhead time to lock in on a transmitter doesn't take much time nor does it subtract much from the actual data (video) transmission time.

To work with SS, either Direct Sequency or Frequency-Hopping, one has to think in terms of TIME rather than frequency. Once that can be done you will find lots of such examples in the wider field of radio-electronics done over the last half century.

Picking up a project that has been put down for 6 months - has
anybody got experience of manufacturing their own ATU
switches out of brass, either as knife switches or else as
ginormous banana plugs which then engage axially with
a sliding action?

I have conceived of a design for an experimental ATU that
allows changes of configuration (including the safety earthing
when not in use) using only 8 single-pole single throw switches,
into the most common configurations.

(I may have mentioned this before in this NG, sorry if so and
thus inducing ennui in my loyal-but-paranoid fan-club of CB types
who seem to hang on my every word)

I have no doubt that the military came up with some sort of lacing
machine. ;-)

> I bought a package of 100 Ty-Raps at DoItCenters couple months ago

> awning. Tubing is very soft, about 1/4" diameter. 8-inch tie wraps,
> standard white nylon material. No problem. No stoppages, no
> damages, but didn't try to put a full arm's strength into completing the
> tie. :-).

<snip remainder>

The reference to 'fragile' coaxial cables was made in regards to
the Teflon-jacketed stuff in use in aircraft, not conventional RG8 or
others. I should have clarified that a bit.

It was found that some types of insulation (notably Kapton) show a
greater sensitivity to arcing if they have been nicked or scored, even
slightly. Ty-wraps, if not properly used, are more likely to do this
than lacing, especially in a vibration environment. This is why they are
not generally favored for aircraft wire bundles.

While I agree that neatness was certainly one of the reasons, it
was not the only one.

I would be most interested to hear what anyone working in CURRENT
wire design on aircraft has to say about the subject.

Keep the peace(es).

Well I would say that if mobile phones are eventually proven to be bad for your health, it is most likely to be the phone itself that is the culprit rather than the mast mounted tx at the local school etc; a point that still has not been made by the media or, it seems, anyone providing them with information.

It is probably worth noting that, in my experience, most children use their mobiles almost exclusively for 'texting' rather than 'talking'; presumably this carries significantly less risk perceived or otherwise.

I agree. Proximity is the dominant factor at work here. That's why
these scare stories about mobile phone masts and cancer are such
total nonsense.
There may well be some significant risk associated with the
conventional use of mobiles right next to the head, though. The EM
field is bound to invade brain tissue and the effects of such exposure
to even low levels of near-microwave frequencies are as yet not fully
known.

Therein lies a problem; I had considered the use of 270MHz
SAW filters as used in GSM phones as RX roofing filters, but
with the deign of GSM phones moving en masse to direct
conversion, that's not possible.

One area in which we can assure some degree of future proofing
is to define the interfaces between the sections so that any
section could be replaced by circuitry of your own making
and/or of your own repair.

It is legal, provided you use the FCC-approved spreading polynomials
and whatnot and hold your mouth right. So long as you do it the FCC
way, they have no trouble monitoring.

You really are a prize fool. The invention of the Thermionic Vacuum
Valve (tube) held up the development of transisters by around 20 years.
They were shit in the 30's and are still shit today. Just think what we
could be doing now, 20 years further down Moores Law curve.
You are living in the past Bean.

Dear Airy,

I can't resist the temptation to read most of what you write. It's habit forming.

It's because there appears to be an unexpected element of truth in many of your thought-out if unruly statements.

But try not to be so offensive in your, chip-on-the-shoulder, mode of expression. You could be even more effective.

Reg.

==========

The trouble with as many as 8 single-throw, high-current, high-voltage switches in a tuner, is the stray inter-component wiring and inductance and capacitance they introduce.

Even with a minimum number of, or no switches, it requires TWO independent tuners, in separate boxes with separate coaxial connectors, to cover the range 1.8 to 30 Mhz with reasonable power efficiency.

You need practical experience by building one or two to see how they perform. Try again and then come back!

Reg.

I see. Well we're not governed by the FCC here in Little Britland, so
I guess it's probably illegal to use it in the UK. Perhaps a G with a
licence to hand can verify...

Yes, it's a usual load of Tosh, the opening paragraph says it all, even a so called expert admits he doesn't know.

"Parents should ensure their children use mobile phones only when absolutely necessary because of the potential health risks, an expert is warning."
Then in same sentence,

"The latest study by Sir William Stewart says there is still no proof mobile phones are unsafe,"

The vision of angry villagers with flaming torches spring to mind every time I hear about objections to mobile phones/masts.

Would a solution based on two, contra-rotatinng "roller coasters" not be
better? This would enable a true balanced ATU to be made, offering a wide
matching impedance, and, with motorised capacitor, avoiding switching all
together?

Making a suitable capacitor is straight forward. The rollor coaster former
will turn up on a lathe nicely (I've made a similar former from PTFE in the
past). The rest of the mechanics are easy enough.

Which is why I was considering the use of axially operated
banana-plug-like switches which would then exist in-line with the
wiring, and be operated by fishing line (in a sort of pull-in/pull-out
mode).

Knife switches of sufficient mechanical movement would also serve
to reduce capacitive coupling when open. Now that I mention it, I
do seem to remember discussing this before, especially with regard to
springy brass for knife switch contacts.

A woman goes into the chemist, "Does that Viagra really work?"
"Oh Yes! Madam! I can vouch for its effectiveness personally!"
"Can you get it over the counter?"
"I can if I take two!"

-----ooooo-----

A man reaches over the counter and steals some Viagra.
However, on rushing out of the chemist's, he bumps into a plod.
In a panic, he swallowed the whole contents of the packet and
ran off.
The plods are looking for someone with a very stiff neck.

-----ooooo-----

Because of concerns about corruption in the NHS, doctors are
no longer allowed to prescribe Viagra, as such, they have to
specify it by its chemical name.....
.....
.....

Dear Reg,

Thank-you for your few kind words.

I, in my turn, read with interest your contributions to the
various NG. From what you profess, I have much to
learn about the common sense of what really happens
in antennae and feeders and I am an avid pupil of yours.
(That is part of parcel of Ham Radio, not only to
improve one's own knowledge, but also to encourage
others in what is essentially a technical pursuit.)

As to offensiveness, none is intended. If it was your
intention to refer to my stance against the gangrenous
degeneration that is the M3/CB Fools' Licence scheme,
then I regret that I can offer you no apology. We Radio
Hams must take a stand now, and that stand must be to
refuse to have anything to do with what are essentially
second-class citizens in the radio context.

In other matters, if you do indeed refer to other matters, I speak
my mind and I speak the truth as I see it. Do not be so
surprised at candidness and openness. (If there are those
who take the liberty of taking offence at ideas expressed
that are not their own ideas, then they would be well advised
not to read an international forum such as this NG.

Caveat Lector.

If you're not up to hooking up a LCD controller and a receiver then
your only real option is a videosender receiver.

PN
>sequences on both ends.

While I can't give you a detailed example of how a portable field radio
(such
as the U.S. military's standard small-unit SINCGARS), there are a host of
already-working-for-a-long-time examples. One is the ordinary modem which
has both a "fast clocking" (almost like coarse acquisition) initial
synchronization that stabilizes the receiver decoder's internal bit rate,
then
an actual sync decoder from that to "line up" everthing.

With repetitive digital signals incoming, an ordinary modem borrows a
technique from magnetic data recording to set the decoding bit rate on the
transition of each pulse. Usually that is done at twice the bit rate to
grab
either transition. That can be a simple PLL with emphasis on the Phase,
but it can also be a simple R-C differentiator thing since the initial
timing
doesn't have to be precise. Once that is locked into place, the "fine
tuning"
for time synchronization can be done in several ways. One way is very
much like the old radar/transponder "coincidence detectors" which run a
pulse pair into a delay line and look for an AND (or coincidence) of the
input with the output, the pair's spacing equal to the delay line delay.
That
old "analogue" method was done in prehistoric times of tubes/valves and
useful in aviation radionavigation (IFF transponders, DME, all of which had

to coexist with unsynchronized pulse pairs from other interrogators).

A more modern way with digital logic is to use a multiple-stage Shift Register, clocking the S-R with the "coarse" bit rate achieved with the first data stream arrival. The S-R outputs can be Exclusive-ORed with the incoming signal and all the Ex-ORs ANDed to select the coincidence which was known for that particular system. The versatility of that is being able to
pick any sequence pattern of 1s and 0s desired to get that "time sync" (some prefer "framing" synchronization as a term) to get in step with the transmitter
signal. Once that framing lock has been achieved, it is not difficult to keep a
crystal oscillator phase-locked to the incoming bit rate (NTSC and PAL TV do that). The framing sync lock pattern could be 4 to 256 bits long, whatever
is system-desireable and there are no great demands on timing accuracy for that (fairly easy to work out if thinking in terms of time). With phase-
locking internal to the receiver, it aligns itself to the transmitter, no sweat.
There are no great demands on jitter specs to get initial bit rate sync or even to get framing sync; once the first sync is done, the system can fine tune itself to stay in timing.

A "framing sync" pattern is slightly wasteful overhead in that it can't carry
any data during its existance. From there on, there's all kinds of system variations possible depending on modulation rate, sampling times, time-multiplexing (if used), and all kinds of other things. Once a Tx-to-Rx sync has been achieved, the data portion can be tailored to fit...along with the internal stability necessary to limit the number of framing sync sendings to maintain a good lock. In the initial acquisition of a signal there's bound to
be some time wasted for the Rx to get in step with the Tx signal but that is quite short indeed despite a wide variation in such system architecture.

The ubiquitous "keyless" auto lock is an example of a very secure (through very long) digital bit pattern. Bandwidth isn't very high despite being UHF (for keyfob size packaging) but it does the whole works and determines the correct lock/unlock sequence (along with the convoluted decoding thing for security) very quick - does it before that one "squeep" of the horn
or speaker sounds.

Those of us who've worked with aircraft DME (Distance Measuring Equipment) will have seen the ability of simple pulse-pair "coincidence detection" work through a mass of "fruit" (pulse pairs from dozens of other aircraft) to pick out the time-delayed ground station response. No PLL needed there. The return signal is seen like right away on a scope, the scope synchronized to the DME interrogator signal. I've

forgotten the ARINC spec but it's like 200+ aircraft can be interrogating the ground station at the same time (ground station replies with a fixed 50 uSec time delay) and nobody interferes with anyone else.

In a modern digital example, the U.S. military SINCGARS field radios have an extremely tight spec temperature compensated (like its hard to believe how tight that is) internal crystal oscillator. The "Plugger" (old AN/PSN-11 GPS receiver) can attach to it and update the time to accuracy of the GPSS. Strangely enough, that isn't needed to get SINCGARS sets to work together as much as the precise time is needed to do networking, to get all the "hops" in sync (SINCGARS is a frequency-hopper hopping at about 10+ hops/second in addition to doing digitized voice and data). [see public data on AN/PRC-119 latest models from ITT Fort Wayne IN website] About a quarter million of the SINCGARS R/Ts have been produced since first operational around end of 1989. Extemely secure radio in the field and many can be working at the same time without interference to one another.

In conventional NTSC TV receivers, the color subcarrier sample of only 6 to 8 cycles of 3.58 MHz is sufficient to work the PLL in the receiver for holding on very tightly to that color burst signal. A crystal oscillator is used to insure minimal jitter and maximum phase hold for a single horizontal sweep time (NTSC is most unforgiving of phase errors). "Lost time" due to sending the color burst is only about 2 1/2 percent of a horizontal sweep duration. While that isn't an SS thing it shows that overhead time to lock in on a transmitter doesn't take much time nor does it subtract much from the actual data (video) transmission time.

To work with SS, either Direct Sequency or Frequency-Hopping, one has to think in terms of TIME rather than frequency. Once that can be done you will find lots of such examples in the wider field of radio-electronics done over the last half century.

>>Spread Spectrum = Legalized Jamming.
>
>Is it even legal for hams, though??

Yes, with restrictions. See Part 97 section 311 for the detailed rules.

Briefly:

- SS is allowed, but must not be used for the purpose of obscuring
the meaning of the transmissions.

- SS transmissions must not cause harmful interference to non-SS
stations, and must accept all interference from non-SS stations.

- SS transmissions are limited to 100 watts, and if over 1 watt must
implement automatic transmitter power control which limits power to
the minimum needed to maintain a specified SNR.

- SS stations can be ordered to shut down or restrict their
transmissions, and/or required to maintain a complete record of
information transmitted via SS.

If I recall correctly, the FCC rules used to restrict amateur SS
tranmsissions to using certain specified coding techniques, but this
restriction appears to have been relaxed. I infer that the broader
rule about using publicly-documented modulation techniques is the one
which now applies.

What?

;-)

I heard (no pun intended) that the YAAH committee report states that most of the talk about health being put under risk by mobile phones/mast is totally bollox.

I have to agree, before anyone spouts off about being sick due to a nearby mast perhaps the investigators ought to check the contents of moaners fridge etc first.

> [...]

Hi Dave,

thanks a lot for your reply! And also to Fred for his remarks.

The information regarding the temperature calibration is very helpful. I found a replacement thermistor, which seems to be suitable: 83K @ 25C, 10.24K @ 80C, reaction time 0.7s, size 1.5mm diameter.

As the HP 10544A uses an AT cut crystal I assume that I have to calibrate for a frequency minimum (according to the above mentioned website). As the HP 10544A contains a 10 turn variable resistor instead of a hand-picked resistor, calibration should be quite straight forward.

Thanks again, best regards, 73,
Arnd

Is that 10 years continous use? If so, most youngsters will be death by the
time they are 18, if the 'music' hasn't 'got them by 15 ;-)

I'm glad I'm too old to like what passes for 'music' these days ;-)

I assume you mean deaf? Few people have used cell phones
for ten years already. Some of those few are starting to
get tumors inside their ears. I have switched over to a
headset for my cellphone activities after having one
for about three years.

December 2004, page 20: "Cellphones Linked To Brain Tumors"
"No tumors were associated with less than 10 years of
cellphone use." There will be about 50 million people with
10 years of cellphone use in 1907. I won't be one of them.

Indeed, thinking of something else as I typed. Its the 'music' ;-)

>Few people have used cell phones
> for ten years already.

Not sure about that. The mobile phone was an icon of the 'Yuppie' era (along
with the Filofax, BMW, Rolex, etc.) That was mid 1980s.

I'm pretty sure we one of the early 'next generation' phones (digital) in
about 1990.

Just checked, it One2One launched in 1993, and there were other systems
before that.

Hard to believe, I don't recall a time when we weren't plagued by the
'mobile'.

I smell some faulty logic, just because "No tumors were associated with
less than 10 years of cellphone use" you can not infer that tumours
should be associated with more than ten years use. Since handheld mobile
phones have been in use for over ten years there should be statistical
evidence of tumour induction, in fact give the large proportion of the
population using such devices the stats would indicate some tumours in
less than ten years. Where are they?

FYI on CDMA cell phone systems the base station transmits an
"unspread" pilot carrier for the mobile to lock onto. Once the phone
finds a pilot it starts looking for the sync/paging channel, which is,
IIRC, the "101010..." Walsh Code. Can't remenber now but I think one
of the "rake reciever" channels stays glued to this to keep the
timing.

The base stations obtain thier PN offset timing from GPS synced clocks
at each site, all system timing is based on the "even" second output
from the clocks.

Not sure about the current military gear but it used to take a few
seconds after pushing the PTT before a little beep sounded letting you
know it was OK to talk, but they wern't running at anything like the
spreading rates used today, probably a lot easier to find & sync to
the transmission pattern.

Thanks. Here's what the article really said:

"Researchers at the Karolinska Institute of Environmental Medicine, in Stockholm, Sweden, have found an association between long-term cellphone use and a rare, benign tumor, causing concern among radiation specialists and epidemiologists, though they emphasize that the results haven't been replicated yet. Scientists now eagerly await results from other studies under way around the world.

Published in the November issue of the journal _Epidemiology_, the Swedish study, led by Stefan Lï¿½nn of the Karolinska Institute, looked at 148 people who had acoustic neuroma and compared them with 604 healthy people. It found that people who used cellphones for more than 10 years doubled their risk of developing the tumor, a benign condition affecting one in 100 000 people. . ."

So when you compacted this into the statement that "cell phone use for ten years results in a benign tumor that causes hearing loss", was it an emulation of today's journalistic technique, or just the effect of years spent working with binary circuits?

Looks to me like it said that a single study, yet to be replicated, of a small group of people indicated that long-term cell phone use caused a doubling of the risk of a rare benign tumor, raising the odds of getting one from about 1 in 100,000 to 1 in 50,000.

So when you compacted this into the statement that "cell phone use for ten years results in a benign tumor that causes hearing loss", was it an

emulation of today's journalistic technique, or just the effect of years spent working with binary circuits?

Firstly, you have to ask yourself what is meant by 'ten years of use'.

Does it mean

- owning one for ten tears?
- having it switched on for ten years?
- using it for x hours a day for ten years?

The meaning of 'ten years' hasn't been made clear so far, at least on
this ng.

Then you need to take into account of the mechanics of tumour
initiation and development. There are thought to be five or six events
in the initiation and growth of a tumour to the stage where it can be
clinically diagnosed. Only one of these is associated with the
causative factor, which will have its own rate of effectiveness, and
so will each of the remaining steps.

Unless the statistics have been very carefully researched and
manipulated, and they may well have been, the numbers reported should
be treated with some caution....

If your oven works at 80 degC, it contains an SC cut crystal and not an AT.
AT crystals have their optimum temperature at abt. 28 degC, they are close
to useless at 80 degC.

Just curious, did the study take into account putting vinyl phone
cases against skin, being warmed up & subsequently out-gassing
carcinogens that were then absorbed through the skin & into the blood
stream???

Enquiring Minds Want to Know-

Howard.

p.s.- Just what are "double the odds" for this "rare" cancer? Any
chance they're within the statistical noise floor?? EMWtK.

H.E.

You in the USA already? ;-)

Already I have used an already mobile phone for well over ten years already.
(not too sure how to punctuate that in the USA vernacular) ;-)
I see no signs of ill health in either myself, or my daughter already. We
both went with Orange about the same time. (A British mobile phone network)
Now Orange work at about 1.8 Gig? At that time, that was about the highest
frequency phone system that was going. Now we have systems that work at 3
gigabyte? already. Or do they operate at even higher frequencies already?
I'm not to sure already.

Right! I'm off to bed already. ;-)

Dave

Isn't Orange an offshoot of Hutchinsion Telecom which was, I think, from
Hong Kong?

Actually Dave, Cecil's use of "already" was quite appropriate. Just
because it may not be 'our' English doesn't make it incorrect- for good or
ill US and UK English are diverging. Languages change. In fact, there is
some evidence the US English is nearer to old English than current UK usage.

Not to mention using the MP3 or Radio features with the volume too high. Or
RSI in the thumbs due to over texting.

Even worse, terminal boredom watching phone geeks comparing features. What
is wrong with a basic phone?
Some things are best simple:

Mobilephones (Proud owner of a Nokia 3310.)
Watches (I don't even like quartz watches, give me a mechanical automatic
any day.)
Razors (why do people like electric razors?)
Toothbrushes (electric toothes, I ask you).

I bet that driving a car to work every day raises the likelihood of a multiude of serious health illnesses by an order of magnitude, and those risks are a lot greater than 1 in 100,000 to begin with!

A lot people don't seem to reailze that lifestyle choices (where you live, what you eat, etc.) have a vastly greater influence on their likelihood of coming down with some dreaded disease than most forms of new technology do...

(Although I am all for continuing research so that appropriate levels for polluting gases, EM radiation emissions, etc. can be set... but of course 'the appropriate level' is at least as much if not more a political problem than a technical problem.)

Mainly laziness; the last thing I want to do when I'm still groggy in the
morning is deal with changing a double-edged razor blade.

> Toothbrushes (electric toothes, I ask you).

I'd speculate that _most_ people do a better job of cleaning with an
electric toothbrush than with a 'manual...'

I can't imagine how I live without then. Nice mechanical hands that move, a
nice tick, and not having to wind it up. If cars were as reliable as a
Rolex, garages would be out of business.

I've heard that before. However, there is also the case for 'up and down'
motion (no innuendo intended) and electric toothbrushes are rotary.

It was my understanding that some of the tubes from Russia were in fact made by hand. I would like to know how you progress in this.
In regards to a previous negative comment, what compels someone to write a derogatory comment about someone for their technical ideas? In the Xtals crystals society there is a book on building a crystal set from scratch, headphones and all without purchasing any built electronic parts. More power to people who do it!!!

True, owning for ten years but never switching on can be no worse then
any other lump of plastic and metal. Having it switched on but not
making any calls is also of minimal risk. Using for X hours per day
might be meaningful but if X is not defined it is of little value, we
also need to know what proportion of users suffer adverse effect. If the
proportion is little different to that in non-mobile phone users then
use of mobile phones can not be considered significant.

Personally I use an electric because it doesn't take chunks out of my
face. Not that I do that often with a razor, but you can bet that the
day I have an important meeting is the one I end up looking like an
extra from a slasher horror film :-)

My electric one goes up and down. It is also a completely sealed handle,
with the battery charging done inductively, and the motion transferred
to the head magnetically. I can't believe the amount of engineering gone
into something that could be done with a stick of plastic and a few
bristles :-)
(and no, I didn't buy it - it was given to me).

> What
>is wrong with a basic phone?

Unless you need the extra features, nothing. I have a digital camera
which is much better than any in a phone, my pocket radio is better than
any phone, my handheld computer is better than any phone. My mobile
phone is smaller than any phone containing "feature" I seldom want to
carry around.

>Some things are best simple:

However not automatically so.

>Mobilephones (Proud owner of a Nokia 3310.)

Depends if you NEED more than speech.

>Watches (I don't even like quartz watches, give me a mechanical
>automatic
>any day.)

My analogue quarts is more rugged and accurate but I do have to change
the battery every three years so I do have some sympathy for a
mechanical automatic.

>Razors (why do people like electric razors?)

Perhaps they find the vibration of an electric shaver to be auto-erotic,
I prefer the closer shave obtained with a real razor.

>Toothbrushes (electric toothes, I ask you).

Depends on the type; the reciprocating rotary head are more effective
than an ordinary brush, the vibrating etc. are a waste of time.

I take an engineering approach and select equipment to be effective
rather than simply rejecting anything that is not traditional (otherwise
you would have to reject all phones and use runners).

Hmm... I don't know that we NEED much of any modern technology... but I'm certainly willing to pay for it! (And it is interesting how the Internet has gone from being 'a cool toy' to something many would argue is NEEDed for 'modern jobs' in under a decade... I wonder how long telephones took to reach the same level of 'NEED'?)

Casio has some nice 10 year (battery life) models, although they're plastic so generally the case will die years before the battery...

There are also solar powered and kinetically powered quartz (electric) watches out there...

>455khz sig. I,ve got the whole winter to play
>with it.

The 560 series of scopes could use either 2 or 3 series plugins. Of these, the 3 series were the more advanced, but the 3A72, and a few others, are exceptions. There were several 3A7? plugins, all of which started out as just 7? plugins, and were even more primitive that the 2 series. Consequently, the 3A7? plugins are not very desirable, except for the 3A74, which is the only 4 channel plugin made for these scopes.

I had to look up the 3B2 plugin. I've never seen one, but I found that it was made to provide digital output to work with the 567 and 568 scopes. It is usually paired with the (also digital capable) 3A2, which I've also never seen. It is only a 500 kHz plugin, however.

The 3A72 plugin only has inputs, and this is where you need to feed the signals that you want to display on the scope.

The 3B2 has an external trigger input as well as a couple of outputs, but you can ignore them for most uses.

I'm not familiar with the 568. I doubt if there is a 455 kHz output on it, but I could be wrong. If it's there, then it must have something to do with the digital display unit, which you don't have (and probably don't want, it's just as big as the scope!)

If you want more information on these and other early Tek scopes, including pictures of all the items we've been talking about, there is a good book available on them. Look for "Oscilloscopes, Selecting and Restoring a Classic" by Stan Griffiths. I believe you can find Stan on the web and buy the book directly from him.

3 series plugins sometimes appear at swap meets for very reasonable prices. I've paid as little as $5 for one, but then it required tubes and repairs. I have quite a few of these, including a number of working spares, so if you are interested in purchasing some upgrades,

I probably have them.

greets all

Just wanted to let everyone [who might read this] know that I am looking to purchase a spectrum analyzer. Make and model is not terribly important. Just looking for something that works reasonably well, has fairly good input sensitivity (measurements made from an antenna are prime objective) and has a top end of at least 1Ghz.

I've looked on ebay. Most of these unit are running at least $1000.00 - $1500.00 or over. If anyone's recently purchased a new 6 or 22Ghz SA, and would like to get rid of that older one that might be sitting in the closet, I'd be interested. Thanks.

Dave

People with less than 10 years of cellphone use suffered the same
rate of tumors as non-cellphone users. People with more than 10 years
of cellphone use suffered twice as many tumors as non-cellphone users
and tumors among cellphone users was four times more likely to occur
on the side of the head normally used for the cellphone. Where's the
faulty logic?

|>> wrapped cables.
|>>
|>> --
|>>
|>> 73
|>> Hank WD5JFR
|>>
|>
|>What is cable mining?
|
| New cables are laid into cable racks on top of old cables, and
| the old ones that are no longer used are just cut off where they
| enter the cable rack and left in place. Eventually, of course,
| the cable rack fills up with old unused cable.
|
| So every decade or so some poor smucks get the job of removing
| all old cables. And that... is cable mining.
|
| It isn't fun and it isn't exciting (but if you get the cable it
| might be profitable though).
|
| And if any of the cable was put in with tie-wraps, you also get
| your hands shredded from the sharp edges where the tie wraps
| were cut off. That is bad enough if a proper tool is used, and
| *far* worse if some dingbat has used snips to cut them.

I've had to do that under computer room raised floors. New computers come
in before the old ones leave and cables get laid on top of existing cable.
When the oldest ones eventually do get decommissioned, the cables are at
the bottom and too hard to get out. Eventually they pile up. This was in
the mainframe days when a computer _system_ involved a "CPU" the size of
your living room, and a hundred washing machine size peripherals that
would fill up a large house, all on hundreds of 2 foot by 2 foot squares
sitting on a grid of poles and crossmembers. At one place I used to work
we decommissioned an entire machine room which was being converted to
office space. All the cables did have to be removed in that one, and
there were some interesting things found deep down. Mainframe cables

were quite large, BTW.

More on the subject from:
http://www.timesonline.co.uk/article/0,,2-1436543,00.html

"CHILDREN under the age of eight should not use mobile phones, parents were advised last night after an authoritative report linked heavy use to ear and brain tumours and concluded that the risks had been underestimated by most scientists.

Professor Sir William Stewart, chairman of the National Radiological Protection Board (NRPB), said that evidence of potentially harmful effects had become more persuasive over the past five years.

The news prompted calls for phones to carry health warnings and panic in parts of the industry. One British manufacturer immediately suspended a model aimed at four to eight-year-olds.

The number of mobiles in Britain has doubled to 50 million since the first government-sponsored report in 2000. The number of children aged between five and nine using mobiles has increased fivefold in the same period.

In his report, Mobile Phones and Health, Sir William said that four studies have caused concern. One ten-year study in Sweden suggests that heavy mobile users are more prone to non-malignant tumours in the ear and brain while a Dutch study had suggested changes in cognitive function. A German study has hinted at an increase in cancer around base stations, while a project supported by the EU had shown evidence of cell damage from fields typical of those of mobile phones."

The faulty logic was in the presumption that ten years use was different when your statement in Message-ID: <41e43ad6$1_1@127.0.0.1> of 'December 2004, page 20: "Cellphones Linked To Brain Tumors" "No tumors were associated with less than 10 years of cellphone use." There will be about 50 million people with 10 years of cellphone use in 1907. I won't be one of them' which made no mention of effects either use for more than ten years or non-use. I do not expect anything a simplistic as a step function at the ten year threshold, perhaps this like your previous post is also omitting essential information?

You may have given too much credence to rumours about tubes like the GS35 (photo on my website).

The anode cooler only *looks* like it was made by some be-whiskered traditional Russian coppersmith, on a side bench in People's Samovar Factory No 23. The grid only *looks* like it was hand-knitted by his wife.

The latter is definitely not true. It's made from a tea strainer.

>A proposal for the body of Hams that make up this

>NG is that we club together and conceive of a design

>for an HF transceiver that could form the basis of the

>station of any budding Radio Ham.

Interesting! If Hairy R. Beanz has anything to do with it then it would indeed be an unisual rig. Synthesiser whine, or any other whining would have to be encouraged. The PTT switch would have to be rewired to a PTR (Press To receive) switch since listening would be only used occasionally. The microphone would need to be large - it would have to be HUGE, - Large enough for even Hairy's mouth. the output power would need to be meggawatts to make sure Hairy can impose his views world-wide (as he is doing now). The modulating system would need a digital sound recorder so the same views can be repeated over and over, again , and again, and again ...

The club that Hairy is proposing would also be a big one, especially when one considers the membership. I would hate to be in the club room at the weekly club meeting, but then again, Hairy would probably introduce club subscriptions. Then there would have to be a club "constitutional" so Hairy could have his "daily constitutional", which would probably mean fitting the newly designed rig in the toilet.

Naaaa. Count me out. The "acid toungue" would also require a special microphone, and I, for one, am not prepared to contribute anything to this project to make a free rig for Hairy R. Beanz.

Unlike heavy mobile phone use it has been proven that increasing Oxydisation of cell structures causes, cancer, aging and ultimately death. Doesn't stop anyone breathing though does it? If we al stopped breathing there would be no cancer, no aging.

Seriously though, as an illustration, say that in 20 years time we find that the heating effect of RF from mobile phones provides a catalyst for increased oxydisation in the brain when combined with the inhilation of plastics vapour from the material used in cellphone keypd membranes to cause cancer of the nose (it could happen!!). This would be a totally unforseen risk to our health. What this report says that is as a precaution to unforseen health risks it is better not to let childern use mobile phones and audults only when absolutly necessary and to limit use. This is an example of the "precautionary principle", specifically used to limit or halt future crisis.

Although meant humorously, it should be noted that oxidation is a process that doesn't necessarily involve oxygen at all!

Oxidation is the process of losing one or more electrons by an atom (which may form part of a molecule) - the species that gained the appropriate electrons is said to be 'reduced'. Redox reactions are a basic part of chemistry.

The real oxidation damage to human cells comes from the action of 'free radicals' - molecules that have gained a lone electron. These electrons are highly reactive, and the transfer of this electron to a molecule in a cell can cause (chemical) damage. If this happens to be part of the cell's DNA, then the 'message' encoded by the DNA has been altered.....which can lead to uncontrolled cell growth and reproduction, and hence The Big Casino.

Where do free radicals come from? Currently they are though to arise through pollution, fried foods, alcohol, sunlight, solvents, ionising radiation, the sources are many and varied. What can you do to prevent free-radical attack? Avoid free-radical producers, and ensure you take enough anti-oxidants through dietary supplementation....

The interested reader is encouraged to find out more through, e.g. web searches. There's a lot of info out there.

I've laboured this a bit because there are people on this ng whose level of understanding is such that they believe things like 'dehumidifiers absorb heat.....you can use this to warm up your shed'.

I didn't say there was a step function at the ten year threshold
and I'm certainly not going to type in the entire article. It is
much more likely that it is a ramp function roughly emerging from
the average after around ten years of use.

The receivers which ship with 2.4GHz wireless cameras may be available separately, but only cover the 2.4-2.5 GHz area. Typically 4 channels. To be honest. the LCD although looking good isn't really vital since video is so wideband that you'll soon get to remember which is which, and a small tuning error isn't the end of the world.
I would suggest investing in a good high gain aerial though (I use a 20dB gain parabolic (cheapest about 40 UKP for a mesh one, if you don't fell like making one). You can use those for 802.11b wireless networking, since this operates in the same band.
David (G7VDI).

That was the company that created it, then sold it to British Aerospace, who
in turn sold it on again. It is now French (spit) owned.

> Actually Dave, Cecil's use of "already" was quite appropriate.

That was why I included the smilies. I find it kinda cute that English in
this country has modernised, but that English spoken over the pond is stuck
in the 17 century.

> Languages change. In fact, there is
> some evidence the US English is nearer to old English than current UK
usage.

Once again, I find this fact hard to understand, when the world's fastest
growing technology, with the worlds largest budget etc can't up-grade the
language it speaks, to what the rest of the English speaking world use.

Regards

Dave

Of course a proportional function is more likely although perhaps not
linear however your statements that "No tumors were associated with less
than 10 years of cellphone use" and "People with more than 10 years of
cellphone use suffered twice as many tumors as non-cellphone users"
describes a step function at ten years {t = 1 for y < 10 and t = 2 for y
> 10, where y is the number of years and t the base rate for brain
tumours in a non-mobile phone using control group). Given this
simplistic step function I must have doubts about the accuracy of the
study that lead to such a conclusion

I do not expect you to type in the entire article, but you only stated
"No tumors were associated with less than 10 years of cellphone use"
which provide no information about any association after ten years.

How exactly could transistors have been developed if tubes weren't
already around?

Manufacturing semiconductors involves induction heaters to melt the
silicon/germanium during the refining process. Large induction heaters
to this day still use big honking TUBES to generate RF power.

Not to mention all the tubes in the test equipment that was used to
develop transistors....

Your basic ignorance of statistical data is showing. What if, starting
at ten years of use, 1% of cell phone users suffered 1% more tumors
than non-cellphone users and a year later, 2% of cellphone users
suffered 2% more tumors than non-cellphone users, and a year later 3%
of cellphone users suffered 3% more tumors than non-cellphone users
... That is certainly ***NOT*** a step function, to which you objected,
but a ramp function that is certainly something to be concerned about.
Hint: I'm surprised that you don't know that nothing changes
instantaneously in reality, i.e. a 'step function' is purely an
invention of the human mind.

>instantaneously in reality, i.e. a 'step function' is purely an
>invention of the human mind.

If, as you state, it went from nothing below ten years to two times
after then there was a step, it is that I object to; perhaps you do not
understand that it is a step {t = 1 for y < 10 and t = 2 for y 10,
where y is the number of years and t the base rate for brain tumours in
a non-mobile phone using control group)

Hint: YOU quoted a single value for less than ten years and single value
for above, maybe you do not understand that is a step, do I have to draw
a graph of your statement.

t

2 ----------------------

1 ---------------------------
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 y

Can you see what happened? Of course I object to the function you quoted
as being improbable.

Your example of a proportional relationship is not justified from your quotes, is irrelevant, and being a deception has no place in a discussion of this nature.

No, you should get in touch with reality. Discontinuities,
like step functions, exist only in limited minds, apparently
like yours, certainly not in reality.

It was you who described a step function and I am disputing it precisely
because it can not be as you describe, why don't you admit that your
description is wrong instead of pretending that you are not, or are you
to stupid to understand that you are wrong.

Was it not the case that the principles of the FET were
established in the early 1900's?

As to test eqpt, surely a red herring, for where did the
valves (tubes to the non-English-speaking Yanks) come
from to make the test eqpt to test the first valves?

In any case, ISTR using transistor test rigs that consisted
of meters, resistors and batteries only. (In the days when
we got hold of manufacturer's rejects and had to sort out
the still-usable ones)

The Mongolian Hordes of CBers are present in Britland,
particularly in the shape of the gangrenous degeneration that
is the M3/CB Fools' Licence scheme.

If we stand aside and let them take over, then who will
speak out for the excellent technical pursuit that is Ham Radio?

Yes - the NG uk.radio.amateur has become largely a CB
group, not the least reason being the sometimes-vicious
and always-infantile abusive tirades from those who
are CBers in one guise or another, as overt CBers,
as M3/CBers and as CBers-Masquerading-As-Radio-Hams.

Do we let them sweep away all that is excellent about Ham Radio,
or do we take a stand against them by staying in, and continuing to
demonstrate our own standards in, the NG uk.radio.amateur?

I wonder if there is any mileage to be had from adapting
the numerous junk-mail CD's as the vanes of ATU
capacitors?

1. We already have a form that is circular (no waste) and
with an accurately-positioned central hole.

2. There is a metallic film sandwiched between the plastic.

3. Is this film to thin to stand up to the RF currents that
will spread out across it when charging & discharging?

4. How would we make metallic contact to the film without
destroying the film at the point of contact?

5. Does anybody know the type of metal making up the film, i.e.,
can we solder to it?

6. Is the plastic of a suitable quality? Will it arc-through?

I make mine into Christmas decorations.
Stick in pairs using double sided foam pads, on monofilament fishing line.
Dangle a lot of these strings inside a window.

A little Googling would soon show you whether the critical factor,
which you doubtless have already determined from your preliminary
calculations is the loss tangent for the CD substrate, may well render
such a use as inadvisable.

Sorry, until you choose to tell the truth, I have
nothing further to say. What I described was a
ramp function starting at 10 years of use. It was
you, not I, who introduced the *step* function
concept.

Superficially the idea has some merit but you would have to machine the
discs anyway (they are totally symetrical and thus the area overlapping with
the fixed vanes wouldn't change). By the time you've machined then to be
asysmetric, might as well have made metal plates and avoid all the other
problems as well.

To problems in making variable Cs, the use of a CDROMs offers little.

Etching plates on PCB and using the fibre glass for the mechanical side is
maybe a better idea.

If you find these 'slicers' in cables which you must handle, you can usually blunt the sharp edges by heating each with a lighter...or maybe a soldering iron with an old tip. (Some high-quality cable ties resist melting.)

I once had to deal with a 100' cable which was completely cable tied. After one time of coiling that monster, I went through the entire thing with a cigarette lighter...

...no more sliced palms!

I wonder what the background to you idea is?

New approaches to existing designs should offer one or more of:

Cost savings (cheaper materials, less man hours, ease of manufacture etc)
Better reliability and/or life (not the same thing by the way)
Extra functionality

For most things, the cost of materials is not a cost driver- the cost of the material in a variable capacitor is dwarfed by the labour and machining costs.

So, how does using duct tape help?

The CD idea falls flat as, while they may be cheap, the amount of machining 'saved' is mininmal. I suppose if you are totally strapped for cash, out of work and with time on your hands, they may offer some advantage, but you end up with a 'product' of inferior quality. Engineers who are driven by such a penny pinching approach usually end up bankrupting their company as their products are poor.

On what basis do you claim that a variable capacitor fashioned
from junk-mail CD ROMs is a "'product' of inferior quality"?

From the power handling capability?

From the flash-over voltage?

From the max and min capacitance?

Which companies do you say have been bankrupted by looking for
economical means of production? (Not all of us can boasts that we
are employed by profligate defence companies and are proud to
have been involved in the development of the weapons that
were responsible for the deaths of so many innocent children
in Iraq, OM)

Or is your posting below yet another example of bullshitting,
of side-stepping and of downright lying?

I have a small supply of new old stock 2N3553 NPN transistors I'm offering for sale.

You can see a datasheet on the 2N3553 at:

http://www.oselectronics.com/downloads/2n3553.pdf

I'm selling them in lots of 10 pieces for $22.00 INCLUDING DOMESTIC SHIPPING. There is an additional $2 charge for overseas shipping.

PayPal gladly accepted.

With my thanks and kind regards,
Dave KB9YOZ

It didn't used to pay to be "the" female apprentice as
females are supposed to have nimbler fingers, a greater
attention to detail and more patience for doing mundane
repetitive work. So, whereas the guys could get away with a
half-assed job, I got to see the same loom time and time
again... Or it could just be I missed out that bit of the
genes...

Sue

Sounds rough. Although I do recall having to tear out all the lacing for a
run of large guage black power cables because they 'should' (to meet
specification) have been laced with red twine and were not! IIRC we used a
waxed Irish lacing twine in at least two thicknesses, usually 'natural'
unless red or black was specified by the customer. The customer in the above
instance being the General Post Office, who at that time operated the United
Kingdom telephone system.
Until and even after approx 1953, each individual wire and the cable
covering fabric; often silk and wool insulated; with the cable ends dipped
in wax before individual wire stripping and terminating!
Then plastic insulated wire was introduced. Cable forms (harnesses) were
made and a girl sitting at a machine on a raised platform, that heated the
ends of the wires, operated it to 'hot strip' each wire (or group of wires)!
Respectable girl though she was she inevitably got nicknamed 'The hot
stripper'.
I do also recall in those days plastic insulated wire/cable was far from
perfect; there was a story about a large form (i.e. bundles of multiwire
cables, laced together in layers on a cable runway), that had been installed
near a warm air heating duct in a telephone switching centre. The many
cables slightly melted and fused together in a big slightly sticky mass.
Eventually wires migrated through the soft plastic and touched together.
Cor; what a mess that must have been!
Inevitably the stitching/lacing would then be immersed in the now fused to
gether plastic! Layers of cables still laced to each other and on the bottom
laced to the steel bars of the cable runway!

Good grief...now there are "Technical TROLLS" from the person
wanting amateurs to get into the vacuum valve fabrication. :-)

>1. We already have a form that is circular (no waste) and
>with an accurately-positioned central hole.

Goodie...now you can make a 360 degree variable capacitor
with an extemely low minimum-to-maximum capacitance
ratio.

>2. There is a metallic film sandwiched between the plastic.

Not really. You can read all about it in free downloads from
the Philips people who developed the recording system.

If it were really conductive, you could measure it directly with
a simple Ohmmeter. [not exactly rocket science, old boy]

>3. Is this film to thin to stand up to the RF currents that
>will spread out across it when charging & discharging?

First you find out what you think is a "metallic film," then you
can conjecture all you want. Hint: What you see on plastic
is not necessarily "metal."

>4. How would we make metallic contact to the film without
>destroying the film at the point of contact?

Use metal-free solder? :-)

>5. Does anybody know the type of metal making up the film, i.e.,
>can we solder to it?

Do you have a soldering iron? Can you not use it?

Or are those FREE, no-cost-to-you CDs so valuable that you
cannot do a few-minutes-of-your-time experiment on your own?

>6. Is the plastic of a suitable quality? Will it arc-through?

Do you have the smarts to use a power supply to rig up a test to
prove this for everyone? Or is everything you have tied up in the

proposed vacuum-valve production line you've talked about?

========

Those free CDs that many receive have some redeeming features:
They can be coasters for placing drinking vessels on; they can be
"frisbees" for use in playing with a dog; they can make decorative
wind chimes to hang on a porch of those who don't like the sound
of wind chimes. If Paul Bunyan were alive today he might like to
use them as Christmas tree decorations. Other than that and
their excellent use as a time-stable data storage medium,
those left-over CDs are rather useless.

It would be nice if folks in here would share ACTUAL data and
information, not propose a lot of fantasy ideas.

CD blanks are nicely circular and MIGHT make some kind of edge-
friction-drive dial but the center (or centre) hole is non-standard at
about 7/16 inch diameter (1.11 cm). Yes, a moderate machine
shop could make a shaft adapter for it...but that same machine shop
could make a much-superior edge-drive dial out of metal in only
slightly more time. That same machine shop could also turn out
capacitor plates for a variable, the shafts for same, end bearings,
etc. Several firms on both sides of the Pond have done that for
over half a century. [Jackson Brothers in the UK, James Millen
et al in the USA]

Rather than get all fired-up in pipedreaming on the keyboard, try
searching for a "dielectric capacitor" on the Internet. There are
several hobbyist sites which explain how they can be made using
thin polymer sheet plates rotating between two metal plates.
Maximum chapacity change ratio is limited to the dielectric
constant of the polymer (that's "plastic" to you non-chemical
types). Withstanding voltage can be figured from dimensions
and plate spacings using pencil and paper (crayon and cardboard
can be used but not recommended).

Presuming that "ATU" is an acronym for Automatic Tuning Unit,
how in the silly blue heck are you going to make it "automatic"
presuming someone else already solves "your" questions? The
servotuning system needs far more thinking attention than gazing
at used CDs pondering the whichness of the what about them.

Hint: There's already been some very nice hobbyist work done
in regard to ATUs with much on the servotuning system (at least
one made from scratch) plus the sensing-detection system to
get the servotuning going in the desired "automatic" direction.
Another Hint: The detection-sensing was solved in 1955 by a
"Yank" surnamed Bruene who was then working at Collins Radio.
[that's in the middle of the USA, in the state of Iowa]

An even better ATU uses a microcontroller chip plus a Bruene
Detector, and some latching relays to switch stepped inductors

and capacitors in/out in a two-element L-C network. Both L and C step in the binary progression of 1-2-4-8-16-... sequence. That sort of network and its micro are at the heart of at least three commercial ATUs built and sold in the USA. It has the advantage of tuning memory, can return to the same setting by actually measuring the carrier's approximate operating frequency! In the U.S. Army such an ATU in incorporated in the backpack HF transceiver AN/PRC-104 (design by Hughes Aircraft Ground Systems, in operational use for nearly two decades). On the ARRL website you can find a reprint of a nice digital ATU construction article that used to be available frree for download but that may have been changed to members-only availability. At the Stoner Goral Company (SGC) website is much interesting information on their ready-built ATUs, installation and use on HF, plus operating manuals (those were free downloads).

www.sgc.com

Founders Don Stoner and Pierre Goral (both hams but sadly, both SK now) developed the SG-2020, a very small 20 W, full-frequency-range-on-HF SSB transceiver, back-pack size almost as small as the PRC-104 (also 20 W PEP).

The step-variable tuning system seems very strange to those accustomed to big handwheel-operated variable capacitors, but that is quite versatile in that you can use readily-available fixed (and sealed) capacitors and toroidal inductors. Toroids are easy enough to make, much much easier than trying to shape CDs into a semblance of capacitor dielectric blades. Toroids can be potted or well coated with varnish, enough to withstand outdoor environments in snow country or the tropics. Relays are generally expensive but Omron makes some nice relatively inexpensive relays (including latching types for built-in memory) for the higher withstanding voltages found with 100 W RF at 50 Ohms with up to 20:1 VSWR. All the big electronic distributors carry Omron products.

Again, It's more than obvious that I said absolutely nothing
about any "step" function. That you believe a tumor can appear
instantaneously as a step function is a mental problem for
which you probably should seek professional help.

An interesting experiment can be performed by placing a CD on top of a
mug filled with water, in an ordinary kitchen microwave, and then
nuking it for about 10 seconds. The resulting "light show" is most
impressive, but also lets out one heck of a stink.

The vaccum-deposited aluminum layer burns up very quickly, and the
spin-coated lacquer on top of it is also damaged quite easily.

The result makes me quite pessimistic that the aluminumization is
robust enough to allow a CD to be used as part of a variable-plate
capacitor in a transmatch, except perhaps at QRP levels.

Part of the problem is that people will respond to his rudeness, if you
can't ignore it kill file him. He does it to disrupt the group and he can
only do so IF WE LET HIM. If we don't let him he can't disrupt the group.
Standard behaviour management.

If we just ignore his rude posts (or the bits of his few other posts that
are rude), the problem would go away. Sometimes some of the stuff I seen
responded to recently hasn't been that bad- maybe his engineering skills are
wanting but this is a forum to ask questions. If he could just stop being so
rude and negative I'd happily try and help him learn.

Thing is, he seems to see every mention of failure as a reference to him. I
can only assume he has very low self esteem. This does make helping him a
challenge. Pity we don't have an SEN teacher in the group- they would be
ideal to advise us on the best plan. He could draw up an IEP for him.

|
| and the nominations are?

Gas (butane) or similar. Don't bother with anything that runs on AAs.

| P.S. could a resistance-soldering rig do it, on battery power,in a
| form factor that's small/light enough to haul up a radar mast in a
| basket?

Why bother? Gas is light, cheap (dollar store) and you could even refill it
up there.

If you believe stating "No tumors were associated with less than 10
years of cellphone use" and "People with more than 10 years of cellphone
use suffered twice as many tumors as non-cellphone users" as you have
does not describe a step at ten years then you are stupid. I do not
believe it can be a step function as you proposed.

"No tumors were associated with less than 10 years of cellphone use."
Translation for feeble-minded people: The graph of brain tumors was
the same for users and non-users for the first ten years of use.

"People with more than 10 years of cellphone use suffered twice as
many tumors as non-cellphone users." Translation for feeble-minded
people: The graph of brain tumors for users and non-users started
to diverge after ten years with twice as many tumors in the user
group as there were in the non-user group.

Statement of fact for feeble-minded people: The above two graphs
were single-valued functions, i.e. no vertical steps existed.

Must be really hard for you to type with that straightjacket on.

how big are the joints?

soldering in the cold can be exasperating.

i use a small oxy-MAP gas torch. it can be a pain dealing with 2 cylinders
but it certainly gets hot enough.

The "standards" for RF safety assume that heating is the only thing
that affects health.

The standard as tested and applied will prevent problems due to
heating - and make the world a safer place for Jello.

I seem to remember at least one case of a researcher in the US turning
up some evidence that low frequency magnetic fields inhibit a bodies
ability to either use or produce "T" cells.

Personally, I don't think there is enough research into it. (and
there isn't likely to be enough)

>Standard behaviour management.

Very good points.

Having posted what appears to be on the surface a technical item
regarding the construction of capacitors for an ATU, it seems that
Bean has done no calculations whatsoever regarding the design.

Even simple back-of-the-envelope calculations would have pointed up
the the critical areas of component performance, which, together with
an appraisal of the limitations of his chosen resources, may have led
to a more realistic redesign. OTOH it may have indicated or confirmed
the correctness of his original approach. But we'll never know.

But did he respond accordingly? Instead of being an interesting
technical discussion, it has become yet another stick with which to
beat selected responders - the 'gentlemanly traditions' disappearing,
if they ever surfaced at all, very rapidly. One is left with the
strong impression that the original posting wasn't meant to be a
technical discussion at all, and another poster's comment elsewhere
about 'the cycle repeats' appears very apposite.

I note that you have already mentioned what could well be the achilles
heel of Bean's choice of components, and one which I was trying to
gently steer him to in my initial contribution. But it seems that it
is more fun to wield the stick rather than undertake any real design
studies. Ah well.

Ends Saturday 1/15 @ 13:12:35 PST (21:12:35 UTC)

A hard to find project box - N.O.S.
http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=5743172645

Still sealed in factory packaging.

Made of rigid 3/32" aluminum, the dimensions are roughly 7" wide x 6"
deep (front-to-back). The height is about 3" in back, sloping to about 1
3/4" in front. Two-piece construction, the side-bottom-side piece is
medium blue wrinkle, the back-top-front piece is a smooth off-white.
Bottom feet and attaching hardware are included.

Thanks for your time, and all the best in 2005,
theponyengine

I think that you will find them available from "RadioSpares", but they are not cheap. I bought one from them a few years ago. Today I would try Farnell in the UK, and I think they even have a catalogue on line :-)

If you do not succeed in the UK, then elsewhere inEurope you could try http://www.elfa.com , which is still in Europe, but not England. Search for product number 49-573-87, which is 1.55mm thick 35 u cu and is 300mm x 400mm. They have even bigger than that (49-573-95) which is 400mm x 600mm.

If you have difficulty getting it, or finding the page, then drop me a line via e-mail at oeieio@hotmail.com as I live just up the road from them.

Have a nice weekend - HM

Hi. Thanks.

If I changed the size that I was prepared to have to 9" x 12" I could get 2
uncoated FR4 (No. 16-21016, 18" x 24"). That comes to ï¿½35.84 (postage
included). So each would cost me ï¿½4.48. Don't know whether that cheap
or expensive not having bought any laminate before.

Think is, how do I cut this? Anyone developed a cheap solution for shearing
PCB laminate?

Oh dear, oh dear, oh dear, you've tried and failed miserably to lead the field with your rather silly outbursts; you've been brought up short, and are now sulking with silly postings like that of yours below. Do you not think that childishly broadcast (CB) jibes such as, "Rather active CB-boy" are at odds with your further comment relating to "a technical amateur radio newsgroup"? Not only at odds, but hypocritical?

Insofar as this is a technical NG, do you not think, perhaps, that the personal attack originated by you below has all the characteristics of trolling?

Stupid Boy!

you cut it with plate scissors, and make the pattern with dentist
drill and a steel ruler, the latter is important support since the
dentist drill is almost impossible to steer without 60 degree angle
against the ruler. It improves the operation with a thin leather under
the ruler
Hope I made myself understandable in a foreign language, have some
remarks on my home-page

All signs of insecurity. If Gareth was sure of himself he could debate /
discuss at a technical level. I can't ever actually recall him doing this.

I'm sure there will be a name for his condition, probably even treatment.

That's real cheap method. :c)

Well, I went ahead and bought 2 off 18" x 24" plain copper clad board from megaUK..com. Don't know why postage for 1 plate of laminate is is ï¿½2.50 and for 2 is ï¿½5.00. Otherwise competitive I think.

Jamie:
The (gas) butane soldering irons are the best for what you want..... the
problem with battery operated soldering irons is that they do not produce a
lot of heat for any length of time.... and usually when you only have a few
more joints to solder, the battery DIES. With a butane soldering iron,
when it runs out of gas you just refill it and you are ready to solder again
in a few minutes.and if more heat is needed just turn up the gas and install
a bigger tip.

Once again, Mr.Reay is brandishing his card with
the "insecurity" sneer upon it.

That Mr.Reay feels the need to repeatedly initiate
personal remarks of an aggressive character, personal
remarks that cannot be taken as "debate / discussion at
a technical level", would seem to suggest that it is Mr.Reay
who is insecure, do you not think?

Also, consider : low temperature solder-- can be melted with a match-
tho NOT advocating THAT technique, would recommend that with a butane
iron, or torch in inclemate weather! And, have used the butane irons
in blizzard conditions, in the Sierras (repairing equipment for the
railroad), useing these. highly recommend them for use in adverse wx!

You are unlikely to get one for free, at least one that works. :) Look
for a clean HP 141T / 8552B / 8554B or 8554L rig on eBay. It should be
possible to find a package like that for less than $600.00. Manuals are
usually available on CD from the same source.

>
> Thanks, Bob

Bob,

I believe that the microphone connector that you are looking for is Amphenol
MC3M (91-MC3M),
which is now manufactured by WPI (WirePro International at their Salem, NJ
manufacturing facility:
http://www.wpi-interconnect.com/salem.htm

The Series 80 & 91 connectors can be found on Page 17 of the WPI
Interconnect Resource Guide:
http://www.wpi-interconnect.com/Resource%20Guide/WPI%20Resource%20Guide.pdf

The Amphenol / WPI connectors are available through the normal electrical
distributor channels:
Allied, Newark, Arrow and ECCO (Chicago)
http://www.eccochicago.com/ecco/index.asp

Here are some sources, in addition to one listed above:
http://l7inc.us/part_91-MC3M

http://www.onlinecomponents.com/search4.cfm?part_number=91%2DMC3M&manufacturer=AMPHENOL&r=
&ref=sparts

This web page (for the JT-30 microphone) also sells the 91-MC3M connector ($
16)
http://www.jt30.com/jt30page/eacstore.html

The Shure 55SH Series II is the current production model:
http://www.shure.com/microphones/models/55sh.asp

Shure does have the data sheets for its discontinued products on-line (great
resource)
http://www.shure.com/datasheets/guides-discontinued.html

Shure 55S, FAQ:
"I have an old 55S, but can't seem to determine what year it was
manufactured. Also, there seems to be a difference in models produced from
1951-1971 and those produced after 1971. What is the difference? When was
the line discontinued?"

1. There is no definitive way to determine the year of manufacture nor does Shure offer that service.

2. There is no definitive list of the product differences over the years.

3. The model 55SH Series II is still made (current production model).

4. The model 55S was last sold in 1978 for $84; first sold in 1951 for $72.

5. A mic collector web site such as www.coolmicrophones.com may have more information.

6. View discontinued mic data sheets at:
http://www.shure.com/datasheets/guides-discontinued.html

7. Shure does not offer opinions on the values of vintage microphones. Value is determined by the collectors willing to buy the mic.

Here are the 1951 and 1971 data sheets:
http://www.shure.com/pdf/discontinued/55s_1951.pdf
http://www.shure.com/pdf/discontinued/55s.pdf

Shure stocks some parts for these earlier models.

Most replacement parts (and many accessories) for Shure products are available through the Shure Service Department, including selected replacement styli (needles) for phonograph cartridges. For information on purchasing these items, contact the Shure Service Department directly. Their phone number toll-free at 800-516-2525 or at 847-600-8688, or contact Shure by email at service@shure.com.
Shure Incorporated
Attn: Service Department
5800 West Touhy Avenue

435. Re: advantages of cable lacing?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-01-15 14:25:40 UTC
From: "Wayne R." <wruffner@KomKast.net>
Message-ID: <cp7iu0ddd42fh2omlid1chiv6cdgujcdsk@4ax.com>
Source record: 20968
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.repair,rec.autos.tech,alt.engineering.electrical,rec.aviation.homebuilt

I do/have done a lot of both in telecom environments. Here's how I see
it:

Lacing:
Pros:
Looks good - only if you know what you're doing.
Keeps old farts happy
Cord is cheap
The few tools required are cheap & low tech
Cons:
Can look crappy after cable/hand 'abrasion'
Lots of labor
Learning curve can be long
Consistency of appearance is difficult,across crews especially
Can cut jackets/hands during installation
Gooey mess from excess wax
Cut ends on floor are sticky
QC inspections can be irrational

TyWraps:
Pros:
Fast
Easy
Looks good - especially if you know what you're doing
Only a single tool (tensioner/cutter) needed
Can be *very* strong
Cons:
Traditionalists don't like it
Shouldn't do it without the right tool
Wrong tension settings can damage jackets/guts
Cut ends on floor are slippery

Clearly, a single, appropriate tool with tywraps makes their only real
problems go away (dykes & pliers are not the right tools for nylon
ties). And while cord is cheap, its labor costs are very high. For me,
there's no choice - tywraps make the most sense.

Right you are, Mr. bean. Some individuals can't seem to separate their personal from their business lives. They need to assign a dollar value to everything. Many of these people, when not at work, do nothing as they dismiss most leisure time activities as an inefficient waste of man-hours.

No. But, then again, it isn't there so I wouldn't have.

If you meant amateur, that work doesn't not mean 'bodger'. Just because you
are doing something for fun is no excuse not to do it well.

I have a selction of different sizes of "soldering Coppers" that I heat
with a torch.
They work good and I can control where I put heat. They are however not
easy
to heat with the torch.

The "cold heat" soldering iron works on the same principle as
an electric welding machine. Thus, there is the germ of a good
idea there. How about a soldering iron using the same principle
as the "cold heat" soldering machine except run off of 110VAC?
It could be transformer isolated, run on low voltage, and thus
be perfectly safe, but with a nearly unlimited source of power
to overcome the battery power limitation.

Since I find tie wraps user-unfriendly for cable that I actually have to handle, but shrinking the whole thing together can be awkward, and make for a very stiff assembly, I'm pleased to be reminded of cable lacing.

I've laced several cable assemblies together now, using dental floss, and that's accomplished exactly what I wanted.

You forgot a couple of biggies on the cons of TyWraps

1. They are not compatable with any fuels or lubricants or hydraulic fluids.

2. They do not survive well in enviroments that are high vibration or those that see very low temps or temps over 100F.

3. They do not age well. They start getting brittle within a couple of years unless they are in a stable office type enviroment.

4. They are totally incompatable with any small fiber F/O system. THey either crush the fiber on install or provide a nice sharp edge for the fiber to fracture against.

5. Cost....My one roll of lacing cord will do the same amount of cable as several thousand TyWraps.

6. Work areas....I can do my ties in locations that you couldn't begin to get a TyWrap gun into.

7. Lacing cord is a one size does it all. With TyWraps you have to size them for the bundle size and tension that you need at each location.

Not to be argumentative, I think these are all good points, but these first two are not completely true. Tiewraps work fine under the hood of a car. They can survive a small amount of oil, and the temp is often easily over 100F.

Of course they don't last forever. As per your third point, they'll get brittle and fall apart eventually. You just replace them before that happens.

> 3. They do not age well. They start getting brittle within a couple of
> years unless they are in a stable office type enviroment.

<rest snipped>

I think the two best tools you can use, to avoid making them too tight, are your fingers and your brain :)

Bob -

The audio response from the 55s is very flat from 150 Hz to 6 kHz which
provides
great reproduction for voice work .... which is also why Shure still makes
this classic after 50 years.

I forgot to give you the restoration pages for this microphone (Shure did
make a version in a gold finish) ..
Darren Pallen Productions is probably best known for this microphone and his
restoration work (using red and blue silk for inserts).
http://www.darrenpallen.com/Shure.htm

History of the Shure 55 series goes back to just before WW2 (photos from
various collections)
http://www.k-bay106.com/shure55a.jpg (1939 - 1946)
http://www.k-bay106.com/shure55.jpg (1947 - 1951)
http://www.k-bay106.com/shure55s.jpg (1951 - 1978)

Ribbon microphone restoration (Larry King and David Letterman have them on
their talk show desks -
although an out of camera boom mic is usually used for audio pickup)
The late Jon R. Sank was the designer for many of the RCA ribbon mics
(highly prized).

Sunlight is Electromagnetic radiation and hardly anybody seems to
mention this when talking about cell phone sand RF safety. Sunlight
also causes heating effects and lots of it. (I know I enjoy it) 1000W
per square metre of radiation hitting the earth on a nice day. That's
a bit more than a cell phone emits I believe AND it contains the
ionizing type of radiation too which is known to cause cancer of
course.

I believe that if there is something to this cell phone thing that it
may be from the electric part of the near field.

I'm certainly not too worried because they seem to have too hard of a
time proving anything. Unlike smoking and lung cancer anyway.

my 2 cents.

If you have something to contribute to the debate, then
discuss it. It is very poor debating to send your readers off
somewhere else.

Besides, I thought that you refused to participate in this NG,
uk.radio.amateur because it was populated only by those, who
in your terms, were CBers.

Are you now admitting to be a CBer?

Is, "LA8AK" some Norwidgian form of the gangrenous degeneration
that is the M3/CB Fools' Licence here in Britland?

Alas, someone with some common sense!

Tie wraps not only will handle a small amount of oil, but will handle lots
of oil and heat! DAMHIK! <g>

In *some* places, you can't beat am occasional tie wrap. You just gotta
have common sense!

Isn't dental floss a little "sharp" (small diameter) for lacing? I'd be
afraid of it cutting into the wires over time.

I disagree with the above. I have used tiewraps in the engine compartment of several cars and trucks I own (one that is now 11 years old) and they have held up well to gas, oil, power steering fluid, etc. They have seen temps from -20F to probably over 180F and are aging well.

Yes, good points.

> 6. Work areas....I can do my ties in locations that you couldn't begin
> to get a TyWrap gun into.

You don't have to use a gun, you can install them by hand, and for sensitive cables in tight areas that is preferred anyway. Much less chance of applying too much tension.

> 7. Lacing cord is a one size does it all. With TyWraps you have to size

I know tywraps are available in lots of different materials. From plain nylon to UV-resistant to Teflon to stainless steel - and everything in between. You're right, you have to make a good choice, and have them when you need them. And a bad selection is expensive, too.

I've only had polyester lacing cord in my hands, and have seen silk stuff for book binding. I can't begin to believe that one-flavor polyester cord is 'omnipotent' in the face of all the yuk and harshness the world offers. What other materials are there? And where can I get some?

I sorta addressed cost in my original list: Cord is cheap, but the labor (time) costs can be way high. Tyes cost more (ok, can be a *lot* more), but go in fast & easy.

And I'm sorry for that crack about the old farts, but you know what I mean.

Apart from being temperature-dependent, terminal voltage is very dependent on recent charge/discharge history. Unless a known regime is implemented before measurement, OCV can be very misleading as a SOC indicator.

Agreed. From my vague recollection, the researcher that was seeing
effects in the immune system from low frequency emf exposure
attributed it to the magnetic field, and was looking at power line
frequencies.

There is some epidemiological evidence that shows a positive
correlation between certain types of cancer, leukemia in children and
nervous system & brain cancers in adults, and Weak LF EMF.

The standard test when it comes to RF safety is for tissue heating - a
cube of gelatin is exposed to the field and heat rise measured. That
assumes that heating is the only ill effect of RF radiation
(forgetting for the moment obvious stuff like RF burns or ozone damage
etc.) - it is possible that there are other, less active, or slower
developing deleterious effects. And that was my point . . .

Like the new approach to pharmaceutical safety in the US - clinical
testing is expensive - it will turn up in the epidemiological evidence
or actuarial statistics eventually - after industry has a chance to
make a profit.

It is unrealistic to expect government to initiate the research until enough people become aware of a problem. That only happens when something is self-evident to a large number of people; and that, in turn, depends on the media to correctly report it.

The W7ZOI design doesn't go anywhere near 1 GHz, though.

There is another homebrew SA design that does, however. Good for the
hardcore builder: http://users4.ev1.net/~wsprowls/index.html

One other one we've run into. Some brands/types of 'Ty-Wrap' use a small metal clip in the blunt end to ratchet against the tong's rack. This little metal clip can/has come out and become an FOD hazard. Ever try finding a tiny 1/8 x 1/16 metal clip in a large FME (Foreign Material Exclusion) area? Not at all fun.

Considering that I have seen Drake 2-NT .. which is the matching CW transmitter for this receiver .. sell for $ 40 to $ 50 (good condition) at recent hamfest and eBay .. why? The Drake 2NT and 2B combo was the premier Novice station in late 1960s and early 1970s

greetings,

I am looking to buy a microwave frequency down converter for my spectrum analyzer.

Avcom MFC-1700 (or equivalent), to convert 1.7GHZ - 2.7GHZ (input) down to 0 - 1000MHz (output). Something close will also work.

Frequency output of down convert must be 0 - 1000MHz (range of spectrum analyzer).

Please e-mail stephanclark001@yahoo.com

Thank you.

I'm interested in building a FSK modem around a PIC microcontroller,
and am wondering how most FSK receivers convert the frequency to bits.
I'm open to a unique solution, and I've seen some frequency to voltage
converters that may work, but would like to know what some current
techniques are that may be a lot more reliable and simpler.
Thanks in advance!
Dave

Hello Mike,

I have been thinking of modifying my HW8 to let it transceive with my Drake 4B for some time (for many years in fact).

There is a plug on the back of the Drake 4B where you get a signal you just have to mix with a fixed oscillator to get the output frequency you need to let the two rigs act as a transceiver. Is there a similar plug on the Drake 2b?

The required fixed oscillator can be realised just by soldering the appropriate Xtal in the HW8, make some changes in the band switching circuits and realign it.

I bought the right Xtal years ago but never took the time to make it work. Now I have a good reason to do so:

I just erected a huge log-periodic beam for all my neighbours to see; so for the next few months I will limit myself to QRP to avoid that they make the link between that huge "thing in the air" and the interferences they could possibly see on their tv-sets.

The toughest part of it will be to find my notes on the subject after all those years (HI), but I will keep you acquainted as soon as I find them.

Kind regards,

Phil

The cheap and sleazy route is what you see many people doing on PICs (and similar) for DTMF detection: To detect a frequency F1, using your ADC's digital output, multiply the digital word by sin(F1*t) and cos(F1*t). Square and add the result, so that you have (ADC_Out*sin(F1*t))^2+(ADC_Out*cos(F1*t))^2. Take the running average of what you get, and use a threshold detector to decide whether or not that frequency is prsent.

The 'cheap and sleazy' part of this comes in as follows:

1) Arrange the frequencies to be, e.g., F1 and F2=2*F1. Sample at 8*F1. Now, all the sine and cosines become +/-1 -- no multiplier needed.
2) Use 'abs' rather than squaring the results -- no multiplier needed.

This isn't particularly robust (it fails rapidly if the input frequencies are off -- the DTMF guys typically don't have to worry about this because DTMF generation is very well controlled), but it gets the job done when you have a relatively high SNR signal and it's very simple and fast to implement since you've gotten rid of the multiplications.

For more narrowly spaced FSK detection, this still works, although you start having to build up tables of sin/cosine values -- and perform the multiplication. If you do have a hardware multiplier around in your particular PIC, this is perhaps still the way to go. If not, you start looking at what resources you do have... you can design more 'proper' digital filters with coefficients of only +/-1 and zero, although sometimes the implementation ends up being more CPU intensive than just doing software multiplies.

Using a tool such as Matlab is very handy for trying our various filtering/detectoin techniques prior to having to sit down and code up the result in C or assembly for a system running in real time!

You could also do this by coding up the digital filters using only shifts. This is not for the faint of heart if you haven't done DSP before, but it can be done and should get you fairly good results. I'd recommend prototyping the algorithm on a PC then making sure that you have enough horsepower in your target processor before you start building a board.

Folks,

I have a homebrew transmatch I got from my Elmer that the
builder provided an alligator clip jumper with.

My question is how is the jumper used?

I posted photos of the outside and inside of the tuner at:

www.nyx.net/~wboas/tuner.html

for your reference. Any advice would be warmly appreciated.
I use it with a Kenwood 440 and a random wire.

Bill, KC0IZI

>before, but it can be done and should get you fairly good results.

With FIR filters and 100-200 bytes of RAM, the shifting needs to be done only once when the sample arrives, by saving each intermediate value after each shift into a table. When the next sample arrives, the old sample table (instead of the original sample value only) is shifted into the next position (tap) of the FIR. This shifting can be done either by block copying or pointer arithmetics.

Since all taps in the FIR have access to all shifted versions of the corresponding sample, all that needs to be done, is adding together those values selected by the coefficient multiplier.

If the tap multipliers are constant and there are sufficiently ROM to have a separate routine for each tap, the elements selected are known at compile time, so you do not have to shift and test the multiplier. Assuming the original sample value is in Shifted[0] and the left shifted values in Shifted[1..7] and the sample value needs to be multiplied e.g. by 19 (00010011) the multiply by 19 routine would be similar to

```
Mul_19:

Add Shifted[0]
Add Shifted[1]
Add Shifted[4]
return
```

Thus,even if the processor lacks the multiply instruction, you only need to make on average 4 additions (for 8 bit multipliers) at each tap. However, the additions must be 16 bit wide for 8 bit samples and coefficients.

It is also 'unlike' in that the link between smoking and lung cancer is
a 100% proven fact (well known since the 1950s) whereas the link between
cellphones and brain tumours is at best tenuous.

Surprisingly, people are suing tobacco companies on the grounds that
'they didn't know' that smoking was bad for you. I suspect that these
are the same type of people who want to ban phone masts, but not the
phones themselves, of course, ie pretty thick!

Your outburst below seems to be self-referential
in terms of bad manners.

There is no association with manners in the free and
personal choice of whether to post at the top or at the bottom,
it's just that - a free choice.

There is nothing that it impolite in exercising a free choice as to
style of presentation - if you think that there is - then you condemn
yourself by being impolite to those of us who are top-posters.

That you choose to target those whose choice is not your own
would seem to suggest that if anybody be the habitu&#65533; of bad manners,
then it is you.

There are no rules on the matter.

Your post below is a shining example of why top-posting is the
better and preferred option, for, in order to read what you put,
a page down was necessary. Another example of bad manners
from you, in fact, because you inconvenience those who just sit
on the "next" button to thumb through a NG.

Source record: 20850

Hi all,

I have, for many years, been making the RX80 amateur band receiver, as published by G3WPO in RadCom in 1980. OK, I know, I am a slow worker. This receiver has a main 3 to 4 MHz tuner module, switchable frequency convertors for the other bands, huff puff vco stabilizer, FM if, and more.

After years laying dorment, I have decided to debug the radio, starting with the main tuner module, and I would like to find some data on the following parts:-

1. Toko KB4412 multifunction receiver IC. This is the heart of the receiver, the part I bought is labelled Uniden, not Toko. It is a 16 pin DIL chip, integrating the mixer, IF amplifier, and detector sections.

2. Plessey SL1621C AGC controller. This is an 8 pin DIL IC which generates the AGC control voltage derived from the audio signal.

I have search the web high and low, and although I have found some references to these parts, I cannot find dats sheets for them. Can anyone point me to the right location, or have a paper copy?

Many Thanks

Pete

Another bad mannered top poster made his insensitive obvious and
ignore good advice so attempt to prove his defective preference
for breaking rules and being a general pain!

What do you need to teach manners? I see your mother failed!
Also you are not even trying!

There are rules by convention. But you choose to ignore them.

Since we are all free to exercise one option. Finding a poster
where there is
no intelligence conveyed! PLONK!

BYE

For someone who is shouting the odds about
bad manners, your outburst below really takes
the biscuit. It is the most hypocritical of rudeness.

Conventions are not rules - if they were to be so, then
everyone, including you, would follow the convention
of top-posting.

As to your rather silly and infantile outburst below....

Firstly, it is random nonsense and complies with none
of the conventions (or, in your own logic, rules) of written
English - hypocrisy once again from you, it would seem.

Secondly, grow up, Clarence!

Stupid boy.

That is only a time displacement. In 1900, after hundreds (thousands?)
of years of tobacco use, the link between smoking and lung cancer was
"at best tenuous".

As many of you know I am fairly new to ham and got a radio to use as a base station this weekend. It is an ALinco dr 590. The guy told me it had been modified to receive and transmit on extended frequercncies even cellular.

I do not intend or want to transmitt illegally but it would be nice to recieve the local police and aircraft if possible. When I plugged it up I could get the frequency of my local police at 452 mhz but did not have an antenna to see if I could hear anything or not. The vhf goes from 130-174 I think. The uhf displays to 500 mhz. How can I tell if this radio has been modified easily?

Also I thought cellular was 800 - 900 mhz. I could not get it to display that.

As a last note does anyone know how I can find online a free manual for htis book? I have looked but only been able to find the service manual. Thanks again!

Computer power supplys are designed to produce a heck of a lot of power
at the processor's voltage, which is 2.5, 1.8, 1.2 or some other
absurdly low figure, and not much at 12V.

Check the surplus places for power supplies: Marlin P Jones and All
Electronics are two good ones in the US.

It is a well know fact that RF modulated with naff TV (East Enders, Big
Brother etc) is rendered safe and has no adverse effects (unless you watch
the programmes).

For those with limited technical knowledge of EM radiation (eg at a level
where they believe in heat bands) the above is intended as humour.

You may want to think through what you want longer term. There are a number of projects around to convert a computer power supply to 12 volts. Might be a bit of a push for a 50 watt radio, I'm not sure. Google for "St. Louis Switcher" or similar.

Supplies are pretty simple, so building one from scratch isn't impossible, but the transformers can be hard to come by.

A cheap commercial supply will give you days of good use. Seriously, there is a lot of pure junk out there, some of it not so cheap. Many of them are very noisy and can put hum on your transmitted signal or make it hard to hear. Some will work for a short while before dying.

Before you make the investment think about your future needs. A good supply can run well over $100 but can last you for decades. Are you going to get on HF and thus need more amps? Are you going to get interested in meteor scatter and need an amplifier for still more amps? Don't go buying a 10 amp supply only to discover that you need another 10 and then another 10. If you decide to go for a good supply go ahead and get 30 or 50 amps worth so your future needs are covered.

Many folks use a marine battery and a trickle charger. This not only gives them plenty of power for the shack, but it keeps them on the air when the lights go out. You need to take care about ventilation and battery leakage, but I don't know anyone who has done this and ever thought about going to a commercial supply. I'm pretty happy with my Astron, but when the lights go out, I'm limited to my HT.

==========
In the UK the 2N3553 is available for GBP 0.95 each
,slightly cheaper than above with P+P paid.

Most of the stuff that I use doesn't seem to care if it is awash in jet fuel, 5606, diesel fuel, Hydrazine or anything else.

As to time, I can generally have my tie run and be tightening it by the time you have selected the correct TyWrap to use.

Here is the cheep and ham way of getting a psu. Try and get your hands on a
BIG 12v charger (a used of the kind used on service stations) 60 -70 amp.
This is the base for your psu. The rest you can find on the drawing.

RFC 1855 - Netiquette Guidelines

http://www.faqs.org/rfcs/rfc1855.html

- If you are sending a reply to a message or a posting be sure you
summarize the original at the top of the message, or include just
enough text of the original to give a context. This will make
sure readers understand when they start to read your response.
Since NetNews, especially, is proliferated by distributing the
postings from one host to another, it is possible to see a
response to a message before seeing the original. Giving context
helps everyone. But do not include the entire original!

It's just a guide - the rest of it is worth reading too....

- Mike

In article <p0olt0dt4veriks2vucuqkrds5l7acpdd5@4ax.com>, Bill Turner
<noway@nohow.com> writes:

>First of all, this anecdote has the ring of untruth.

Roughly about 12 bells all ringing out some jolly tune. :-)

First of all, Air Regulations are in place, have been in place
for decades, to handle aircraft without working radio
equipment. Those are lights in hand-held spotlights.

While it is an Air Regulation that aircraft operating into, over, and
out of air traffic controlled airports must have radios for normal
traffic guidance, there are also safety regulations which anticipate
that someone at some time might have equipment problems.
Flight instructors would surely know that.

In a real-life happening about two decades ago in Los Angeles,
a helicopter instructor's microphone somehow got stuck on
transmit on the normal tower frequency. Having had an aircraft
receiver on in my workshop one Saturday (house is about a mile
and a half from Bob Hope Airport - formerly the Burbank-Glendale-
Pasadena Airport in the east end of San Fernando Valley), I heard
the happening. All listeners could hear the the instructor advise
his student about helicopter hover flying. Somehow the mike
was connected to both the helo intercom and the aircraft radio.

Being AM, the stuck helo transmissions would block all weaker
signals on the BUR tower frequency. BUR tower could overpower
the helo's radio because it was higher power and had elevated
antennas of good size. However, all other traffic was blocked out
for the BUR tower and they had to get a temporary recording
going on other frequencies (approach, departure, radar vectoring)
plus advising VNY (Van Nuys, center of Valley) and LAX of the
problem. The radio blockage continued for about a half hour and
disrupted normal afternoon flying at BUR. How the helo was
informed isn't known but one circulating story has it that an FAA
van drove out to the end of the airport where the hovering took
place and signalled to the helo somehow, perhaps by lights.
The helicopter instructor apologized (apparently when signalled)
over the radio and the frustrated tower operators (at least two
voices) told him, also over the radio, to "report to the tower." :-)

>But even if true, this is a perfect example of the wrong way to solve a
>problem. Instead of relying on Morse for a backup, how about having a
>second radio, perhaps an HT, in the plane?

That's quite common in this area for general aviation aircraft who don't already have two comm radios installed. The Greater Los Angeles section has an extraordinary amount of aircraft traffic. IFR applies to some localized areas. Generally, the FAA can transmit voice over the VOR and/or Localizer in the adjacent radionavigation band (108 - 118 MHz, also AM). The major HT manufacturers all produce a civil aviation model for private aircraft use. Lacking that, the towers have fairly biright aimable spotlights which they can use to signal an aircraft; seldom used, they are there for emergencies. Lacking recognition by a "silent" aircraft, the FAA is prepared to handle it as best as other traffic allows. The FAA air controller's school does not have morse code cognition in its curriculum.

That's correct.

The convention on USENET, and on ARPANET mailing lists such as "info-mac" (the first I ever read), has long been one of "quote the material you are responding to, and put your response after it". That's been the case since at least 1980, and I believe that it dates back even further than that - probably to the first Unix email systems and likely back to the days of email on PDP-11s and TOPS-10/TOPS-20/TENEX systems. In other words, it's a deeply rooted Internet tradition.

I believe this tradition is probably derived from older written-English traditions, such as the "letters to the editor" tradition in which a writer's letter would be printed in whole or part, and an editor's responses to the points made therein being printed after, or interspersed with the letter. I've never seen an editor's rejoinders printed *before* the letter writer's text.

Footnotes and other clarifying comments inserted by a book's editor are likewise printed beneath the text to which they refer.

On the Internet, the use of "top posting" is a much more recent phenomenon. It seems to date to the first arrival of Internet-capable email software authored by Microsoft, a company whom many seem to feel takes delight in ignoring prevailing standards.

One might say that the Internet's "gentleman's tradition" (no disrespect to the ladies being intended by the use of that phrase) is one of interspersed or "bottom" posting, and that those who understand the Internet technical culture and who value "gentlemanly" behavior would choose to respect that tradition.

In an absolute sense, one can argue that neither top nor bottom posting is inherently superior. Howeve, bottom/interspersed posting "got here first" and has been part of Internet tradition for longer than there has been an Internet (big "I").

The comma in "top of the message, or include just" shows that
two suggestions are being made, one suggestion is
bottom-posting and the other suggestion is not.

As you say, "It's just a guide" - not rules, but just a guide.

I see that you conveniently forgot to quote the author's
comments that the quoted bit below was just his own
personal preference and not a rule.

Mmm, cant figure out this new format, so will let fly with probably already said. Lacing looks lovely, and is a skill used to distinguish old techs from young techs, cable ties can cut cable, and can cut fingers as well. Unless there is controlled tension in the cable tie gun, pressure is too variable. Cable ties can start fires, especially when someone puts then round a convenient sharp edged bracket which then cuts into the conductor carrying current. Not nice - very impressive, but not nice.

Lacing should be done with plastic solid core tubing, not waxed nylon or string or anthing else that was used for lead sheath cables in 1930. Phenomena known as "cold flow" where the lacing material can displace the insulation of the bundle. A well done laced cable run is a thing of beauty, and if dressed properly you can virtually trace a conductor from one end to the other. It used to be a trade skill, along with choosing the correct size hammer for "minor adjustments" Ah, the good old days......

This is a 20 amp switching power supply for their 12 volt ham transceivers. I used to leave it on 24 hours a day on receive pulling less than an amp with no problems but about a month ago it started to shut off. You have to turn it off first and wait about 15 minutes and it'll come back on, sometimes for an hour or longer and other times for 5 to 10 minutes. After it goes down you have to turn it off and then wait 10 to 15 and it'll come back for an unpredictable time. It doesn't seem matter if it been on for an hour or sometime 5 minutes, it'll shut down. It doesn't seem to be a cold or heat problem and flexing the board or tapping components won't turn it off or make it come on quicker. I don't have a schematic and can't find one. It must have some kind of logic that senses something and makes it shut down and then time out. One thing I have noticed is that if I turn it on when its not ready to come on I can hear a very, very faint noise (like static discharge) that goes away as soon as the switch is turned off. It has a TL494CN. Any tips appreciated.

Henry:
As long as it is still w"working" the problem is not likely anything more
than either cold or cracked solder connection OR electrolytics that have
dried out or have developed high ESR. If you do not have an ESR meter then
you will have to use the "one by one" substitution method... or just replace
all of the electrolytics at once. Just about all other methods of testing
electrolytics will not provide the crucial ESR test needed especially for
electrolytics in switching power supplies and other high frequency or
critical circuitry.
DO NOT keep running your power supply with this problem.... it will only get
worse to the point that it will fail all together and be a much more
involved repair.

The power supply was turned on this morning at 8 am and shut down in less
than 10 minutes. I turned it back on about 9:30 and it is still on, that's
over 4 hours. I'm not that versed on ESR but I have a tester and cm
curious if high ESR can be an intermittent condition and if so what would
the physics of that phenomena be? At this point I'm not willing to do a
shotgun replacement of all the caps. I do keep running the power supply and
the condition is not getting worse. I wish it would fail so I might find
the failed component. The way it is now it's impossible to troubleshoot
without shotgunning.

I use cable ties for a number of wires (usually power) inside PC's I build.
But one thing I do is make sure I offset the wires from the attached metal.
If the metal is at about a 90 degree angle, then I use 2 cable ties that
wrap each other. If the metal is parallel to the wiring, then 3 cable ties
are used. Lacing would not be very practical inside a PC unless it is part
of a designed manufacturing process where you would have a pre-built harness
or something.

A dried out cap is not an intermittent problem, but if the supply turns
off when some threshold is reached and that threshold has lowered
because of the cap's high ESR then the actual trigger would be caused by
power line fluctuations, temperature changes, etc.

A cold solder joint would be quite intermittent, but it would show up
with board flexing and other "wiggling" kind of diagnostics.

Do an ESR test on the caps. Chances are you will only have a number of bad caps. Sometimes it is best to cool and heat the caps under test. I use a heatgun, and freeze spray to cool and heat them.

This is a 20 amp switching power supply for their 12 volt ham transceivers. I used to leave it on 24 hours a day on receive pulling less than an amp with no problems but about a month ago it started to shut off. You have to turn it off first and wait about 15 minutes and it'll come back on, sometimes for an hour or longer and other times for 5 to 10 minutes. After it goes down you have to turn it off and then wait 10 to 15 and it'll come back for an unpredictable time. It doesn't seem matter if it been on for an hour or sometime 5 minutes, it'll shut down. It doesn't seem to be a cold or heat problem and flexing the board or tapping components won't turn it off or make it come on quicker. I don't have a schematic and can't find one. It must have some kind of logic that senses something and makes it shut down and then time out. One thing I have noticed is that if I turn it on when its not ready to come on I can hear a very, very faint noise (like static discharge) that goes away as soon as the switch is turned off. It has a TL494CN. Any tips appreciated.

Henry:
It is your power supply and your pocket book. If you continue to run it
until it quits altogether the repair will be more involved and probably much
more expensive than just replacing electrolytics or resoldering connections.
It might not gradually get "worse" than it is now, But rather it might have
a catastrophic failure of other parts that are stressed by the high ESR
electrolytic(s) or cracked board connections.... parts like diodes,
switching transistors, integrated circuits, opto-isolator, etc, etc.
Takes your choice and pays your money.

Henry:
Looking for cracked circuit board connections AND testing the electrolytics with an ESR meter (or substituting electrolytics if you do not have an ESR meter) is NOT "shotgunning".... it is real troubleshooting advice as a result of the symptoms you posted. If you continue to use it with the problem you reported it may fail completely and be a bigger repair job.
Pay a little now Or pay a lot later.

Hi Group,

I am working on a project which will detect if a automobile is running. My thoughts are to use a common 455KHz IF filter and amplitude detect or a 10.7 MHz IF filter and do the same.

Which frequency would be better or easier? (455KHz or 10.7MHz)

I would expect that with 455KHz, I could use common op-amps to get the gain up to a good level to detect the noise from the spark plug?

Any thoughts and direction for a direct conversion to something that would turn on an LED?

How about a super-reg? It has a wideband width?

Anyone recall any articles on simple receivers?

How about other frequencies like VHF?

I prefer linear power supplies for this size of radio, such as the Astron
RS-12A. Plentiful at hamfest, surplus and eBay.

IF you find an Astron that is broken and is offered to you for free (GRAB
IT) .. its like being handed money !
Astrons are easy to repair (unless transformer failed - very rare), skip the
Pyramids (many models have under rated heat sinks or electrolytic
capacitors)

Cable lacing was (and is?) common for control wiring in control panels etc.
in the power industry. In that case the signals involved were either 60Hz or
DC and electromechanical relays and meters were used. coupling between
circuits was a non-issue. However, with the advent of solid state devices,
coupling became a problem. One major manufacturer considered a "diode tester
to be a 15 ft lead to a switch or contactor cabled with a lead tied to the

diode. - Open the switch- blow the diode. Wiring was neat and elegant and easy to follow. Circuit diagrams were accompanied by "back of panel" diagrams of the wiring to facilitate maintenance/repairs.
Automotive wiring uses cables for a different purpose- pre-bundle the wires- any jack ass can then push it into place and connect the red wire here, the yellow wire there , etc. Cheap and easy. Maintenance and trouble shooting is the customer's worry -particularly as faults generally appear after the warranty expires (been there) and simply replacing the bundle after the vehicle is built is not that easy.
In PC's etc, it appears that the aim is to cut down clutter- no more -no less- Note that lacing is pretty well confined to the DC side of things (+/-12V, +/-5V, Ground, etc.) - not signal lines.

Imagine someone coming into the middle of the conversation (posting
exchange) and not having already read the quoted part. With bottom posting
they (in particular me) can get up to speed on the thread easier.

Server load, net traffic, etc, can cause news msgs and email to arrive out
of sync with other replies. With top posting you can never be sure of the
order of things you are reading without scrolling up and down a lot. Mix
this with msgs that are part top and part bottom posted and you have a
maze to try to figure out. (I/you/we could argue that however a msg comes
to you - top or bottom posted - you and others who may reply to it should
follow that style for that msg and not mix top/bottom posting)

I'm babbling and probably not making sense. Let me try this - This is how
I see top posting -

Now that I've butted in and caused this thread to drag on longer than it should - Hey! - How about some homebrew radio content!? (technically this should be the start of a new thread with a new subject, maybe I'll do that when I test my antenna some more) I just built a discone style antenna with a lot of radials from 36 inch lengths of wire welding rod. I put it on top of a pole that used to have a bird house on it in my backyard. My neighbors grandfather says it looks like a "sputnic" landed and abducted the bird house.

Reminds me of a horror story I heard at an EMC short course. There was a problem with EMI getting in (or out -- I don't recall) of some equipmant via the 60 Hz power line. So a filter was mounted somewhere in the middle of the device where there was room, and the 60 Hz power was routed through it. Went into production, where they neatly bundled and laced the 60 Hz power leads with a bunch of other wires. The bundle was routed along the side of the filter as it went by. The power leads broke out of the bundle to connect to one side of the filter, and the leads on the other side of the filter rejoined the bundle.

Many low power circuits now use ribbon cables, and in some instances,
if you are not careful about what wire carries what signal, there can
be intermittent cross-talk which can really screw things up. I had 1
case in 10 years where an Engineer had to come over from Germany to
end up building a filter into a ribbon cable that carried a low
frequency pulse. It took him about a week to find the problem because
of its intermittency.

In fact, IIRC, the engineer ended up routing separate wires out of the
ribbon cable to keep the crosstalk out of them. The odd thing about
this case, is out of the hundreds and hundreds of similar machines
with similar circuitry, this was the only unit that had the problem.

It has been my observation that for pc boards and backplanes, ribbon
cable is the way to go, no lacing required. Which leads me to the
question of why automotive companies don't use it in the engine
compartment. It must have to do with the environmental conditions in
there, it isn't *rugged* enough to withstand the heat and abrasion.

You do not need to be convinced one way or the
other. Whether to post at the top or at the bottom
is a matter of free style and free choice.

It is not an issue of gentlemanliness nor of manners.

Rudeness and personal remarks are perhaps of those issues.

Not replying at all is perhaps of those issues.

If someone comes upon a posting in the middle of the
conversation, and wished to follow the conversation,
then he can go to his news server and review the history.

If the posting that he has come across whets his appetite,
then it is most likely to be the NEW contribution that is
responsible for the whetting, and the best place for
this new material is at the top.

If, however, it is the OLD material that whets his appetite,
then, by other practices that are vaunted as conventions, the
old material will have been much reduced by snipping, and the
someone will be motivated to go back to that older posting, and
so it will be irrelevant to him whether that old material is quoted
at the top or the bottom of the new posting.

Of course then there are the Pyramids that can function 24 hours a day 7
days a week from the day you buy it. Mine has been on (except for the
occasional blackout) for over 6 years.

At this apt I turned it on when I moved in and haven't touched it since.

At Hughes, we didn't do "lacing", but used "lacing cord" (flat, waxed, nylon) by the mile. We used spot ties, a precursor to today's cable ties. These were clove hitches around the wire bundle, secured with a square knot. In the production (missile) area, the ends had to be cut, but in the engineering and test equipment area, we would "neaten things up" by melting the ends into the knot with a soldering iron.

Since all the wire was teflon insulated, the ties could be slid along the wire bundles during construction. While still a technician, I once wired a programmer for some TOW missile test equipment. This was back when the highest level integrated circuit was a 7490 decade counter. The unit was basically a timing generator that had four PC board card cages, 30 cards per cage, 44 pins per board, six 72-pin cable connectors and a 24-column x 48-row patch panel. Damn near every pin was used. Timing sequences were determined by ANDing and ORing signals together via the patch panel and then setting or resetting J-K flip-flops. So there was a lot of redundant wiring, ie. one card cage might have 30 identical NAND gate boards.

We used ten wire colors, same as the resistor code, and prided ourselves on having every wire bundle identical throughout its length and to its neighbor. Black wire next to the brown wire next to the red wire.....

As of this moment it has run over 26 hours without shutting down. I've never seen any evidence that ESR can be an intermittent phenomena. Can someone please tell me how intermittent ESR comes about?

You should at least test the electrolytic caps in the startup circuit.

Since as I recall, it blows up only when applying AC power suddenly, something funny is going on during startup.

John -

I have heard that recent Pyramid linear models have addressed these design
issues.
(I have no "hands-on" personal experience to verify these design changes by
Pyramid).
Unfortunately, the used models I see at the hamfests are the earlier models
that I have repair experience with and had these design problems. Possibly
someone will eventually have a web based differentiation guide for these
Pyramid models.

Henry Kolesnik:
It is NOT "intermittent ESR" that is the problem, rather it is that maybe some electrolytics have developed high ESR and are operating just at or near the threshold of the circuitry operating correctly... (see the reply post from Tim Wescott).
At this point you have been given sound technical advice to check for circuit board solder connections and to suspect the electrolytics......
until you perform this important initial suggested troubleshooting there is not much more that you can do ??? Get this fixed right away before it fails completely as you have previously been cautioned.

The measured ESR of an electrolytic capacitor changes with
temperature.... usually ESR decreases slightly. If the power supply
circuit is just at the threshold of operating correctly then very
slight changes in the ESR of critical capacitors will certainly affect
how the power supply operates and sometimes it can cause a catastrophic
failure of other components. Cold or cracked solder connections can
also cause similar intermittent symptoms.
The repair suggestion replies you have been getting to your original
posting are your FIRST troubleshooting and testing steps; otherwise we
are all guessing here.

Just a guess here, as I may have missed a post or two, but does the unit
shut down "completely" to where nothing can be traced through to see where
it stops? IF not, maybe try that too. I agree with the rest otherwise.

==========
A marine battery is fine ,simple and reliable . However if 'trickle charger
' is really a trickle charger ,when operating on FM (with full carrier) the
voltage when battery was fully charged might drop from say 13.8 to 12.8 V
,with battery still being 80 % charged. This means the power input and hence
RF ouput will probably be less than the transceiver's rated power
.............although that probably won't matter much signal wise.
If the transceiver is multimode and when operated on SSB ,the average
current on transmit will be lower resulting in an average output voltage
much closer to 13.8 Volt., even when using a trickle charger.

==========
Score the sheet with a heavy duty blade knive as often used by people laying carpets. You can then easily break-off the unwanted bit .
After that you can smoothen the edges with fine water proof amaril paper (the grey sheet stuff) or simply with a file.

Has worked fine for me.

BTW At radio flea markets on the european continent ,for example in Germany , Belgium and the Netherlands ,large sheets of (usually double-sided) PCB are available for a few Euros. Cut-offs are often sold by weight. There will be a big fleamarket in the Netherlands at Rosmalen at the Autotron Exhibition Centre , date 19 March 2005. Perhaps you can find a Dutch Ham going there to get the stuff for you. This year I won't be going .

==========
It all depends on your type of use .
The 'Slim Jim' is a simple good omni-directional (base)antenna for local comms ,either simplex or via repeater or for local datacomms like Packet Radio and APRS.
The antenna can be easily home-brewed.

You make a good point, Frank. A couple of years ago I bought a relatively cheap battery charger (for the car, not for the radio), and was surprised at what microprocessors have done to these things. Float charging, which is basically what you want, is available from these things pretty commonly now, as well as a myriad of other features. I guess the engineers put a $2 PIC into one of these things and now they got to make excuses to use it. They can't charge a lot less than the next guy so they need to out-feature them. Anyway, the modern automotive battery charger has all nature of features. It has become another of these devices with an impenetrable manual!

> Should I just use rg 58?

You are between a rock and a 'hard place' as both RG-6 and RG-58 will cause incorrect readings on your SWR meter. The first, simply because it will introduce a mismatch and the second because higher cable losses will make the SWR appear to be lower than it actually is. However, if you are just interested in seeing how well you can communicate, use the lower loss RG-6 and work out what the meter readings mean later. Of course, any matching adjustments at the antenna end will have to be remade when you get some low-loss 50-ohm cable. If you were to make the 75-ohm feeder an odd number of half wavelengths down to the bridge though, the antenna's impedance would be roughly duplicated there.

You can calculate the effect that feeder losses have on SWR from the equations in the ARRL Handbook. If you are just going for a minimum then these won't matter as long as you take the final figures with a pinch of salt. Remember that cable losses act twice as far as SWR is concerned and that mismatch loss is higher than straight cable loss.

Cheers - Joe, G3LLV

I am not a troll I just ask alot of questions.

I printed off that copy of the 5/8 wave. It looks interesting but I am
having trouble undertanding its construction.

10 feet of good quality RG58 shouldn't make too much difference,
particularly on 2 meters, but even 70cm should be OK.

I absolutely agree with Tim. 10 feet of RG-58 coax isn't going to mean squat for loss on either 2 or 440. The only difficulty I see is that 10 feet doesn't get YOU too far out of the picture to make a difference in the VSWR readings, especially on 2 meters. Lessee now, 2 meters is about 6 feet, so you are much less than 2 wavelengths away from what you are trying to measure. If you are just looking for rough cut, it may not be too bad, but if you are looking for some fine grain detail, I'd get a bit further away -- like 3 or 4 wavelengths if you have the space.

It is a stacked colinear antenna so has about 6.2dB of gain. Very
impressive. I have it on the roof of my house. We live 150metres from Juan
de Fuca Strait and often catch some very strong SW winds head on. The
antenna is still up and the tuning section hasn't moved!

Basic dumb question:

I read this in passing and am not sure I understood correctly. It seemed to say that you can do image rejection with a quadrature demodulator (by summing the outputs).

For example, feed 11MHz to an IQ demod running at 1MHz. The I & Q outputs will each have 10MHz & 12MHz components in them. Sum the outputs. One of the frequencies will phase-cancel, the other will add constructively. Is this correct?

thx

Stryped-

AOL doesn't have your other message about RG-6 vs RG-58, so I'll try to address both.

When testing antennas, one measure is standing wave ratio (SWR), often read using a "reflectometer" SWR bridge, that actually measures relative forward and reflected power but has a scale calibrated in SWR. You may find more information about this at the Bird Electronics web site, http://www.bird-electronic.com/.

Such an instrument is accurate only if the cable between the bridge and the antenna has the same characteristic impedance as the bridge. For 50 Ohm cable, you need a 50 Ohm bridge. In this case, a resonant antenna with an impedance of 50 Ohms, has an SWR of 1.00:1 (one-to-one).

If you do not have 50 Ohm co-ax, simply make your measurements with the SWR bridge AT the antenna. Even if you have 50 Ohm co-ax, loss due to heating of the cable at higher frequencies will cause the SWR to look better than it really is. Moving the bridge closer to the antenna has an advantage in that case as well. However, using relatively short lengths should not cause much of a problem up to about 150 MHz.

I don't know how to attach PL-259 connectors to RG-6. To attach them to RG-58, you need an adapter that matches the outer diameter of the cable to the inner diameter of the connector. Since the PL-259 is so commonly used with radio equipment, I suggest you keep them and learn about attaching them to RG-58 and RG-8 cables.

The RG-6 is a low-loss cable commonly used in the cable TV industry. As nice as it is, its 75 Ohm impedance will cause serious errors in your antenna measurements if used between the instruments and the antenna. I suggest you steer clear of it for your experimental work. (If you have a 75 Ohm bridge and are working with a 75 Ohm antenna, that is another story!)

Well, I just got rg 8 cable about 20 feet for free! The thing about it it has two pl259 connectors on it. I need to have one end free so i can wire up the slim jim or j pole I build this weekend. I really do not eant to cut the cable as I would like to use it when I put the permanent station up. See any way around this?

Can I use copper house wire 12/ 2 or so to connect to the points on the j pole then bring them to a so connector Then screw the rg8 pl connector into that? Will this through off the swr? What ohms is 12/2 wire?

He also gave me a short cable with two pl 259 connectors to connect between my radio and the swr meter. It was a guy at a motorola dealer. This cable is pretty thin and not rg8 but he said it was 50 ohms.
I plan on hooking the 20 feet from the swr to the antenna.

Yes, that is correct.

However, the choice of frequencies in your demod example is likely to give you other problems not obvious from the basic theory. Harmonics of the 1 MHz are likely to show up in the 10 (or 12 Mhz) output. There are also likely to be many mixing products of all of the harmonics of 1 MHz and any other frequency that can mix with 1 Mhz to produce a 10 (or 12) Mhz output. In general, it's problematic to make a frequency conversion (mixer) process where the LO is substantially lower than the output frequency, and especially so if the LO is an exact sub-multiple of the output.

Stryped-

You said you wanted to make SWR readings. An instrument used to read SWR is also called an SWR Bridge.

Perhaps it is a misnomer based on the use of a simple "balanced bridge" circuit for measuring unknown resistances by comparing them with known standard resistors.

Stryped-

I suggest you obtain an SO-239 connector that mates with the PL-259 connector on the cables. Connect it as close to the antenna terminals as possible.

Once you finish building and testing it, you need some way to connect to it. Why not just make an SO-239 part of the antenna? Otherwise you would need a piece of co-ax to connect permanently to the antenna.

The 12/2 wire's impedance can be calculated, but you would need a handbook to find the formula. It depends on the diameter of the wires and spacing between them. Insulation on the wires may affect the impedance, but probably not very much unless they were twisted together. I think it would be best to keep any such connecting wires as short as possible.

<< This cable is pretty thin and not rg8 but he said it was 50 ohms. I plan on hooking the 20 feet from the swr to the antenna. >>

Smaller cable might be RG-58 if it is a little less than a quarter inch in diameter. If it is around an eighth of an inch, it might be RG-174. If you examine it closely you may find some markings.

Yep, that's the right way to do it. Keep the copper wires as short as possible. Try to find a way to physically fasten the shell of the SO239 connector directly to the point where the shield side of the coax would go, eliminating the house wire on that side altogether if possible.

>Will this through off the swr?

It will, but if you keep the wire short the difference will be negligible. Try to keep it shorter than 2 inches if at all possible.

>What ohms is 12/2 wire?

The wire itself has no impedance.

Two pieces of wire in proximity, and near the rest of the antenna, will exhibit a characteristic impedance. This will be difficult to predict - and unimportant if the length of the wires is kept short.

> He also gave me a short cable with two pl 259 connectors to connect
> between my radio and the swr meter. It was a guy at a motorola dealer.
> This cable is pretty thin and not rg8 but he said it was 50 ohms.
> I plan on hooking the 20 feet from the swr to the antenna.

For the purposes of setting up the match, the "thickness" of the cable between the radio and the SWR meter is not very important. It may cause power loss, but as long as there's enough power to operate the SWR meter it doesn't matter. It may cause the SWR at the radio to be lower than that at the antenna, but it won't affect the SWR at the SWR meter which is where you're measuring it.

Honestly, the way I'd do (and have done) this is by selecting an RF/IF
circuit (which you'll need anyway) that includes a quadrature
discriminator. The Philips SA604/605 family is ideal for that purpose,
but there are plenty of other choices. Quadrature tank components for
common IF frequencies are available off-the-shelf.

My suspicion is that PICs are a bit underpowered for all the DSP hackery
that the other guys are talking about. I could be wrong, though; I have
limited experience with them.

612. Alternate material j pole and questions about dimensions

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-01-21 13:37:58 UTC
From: stryped@hotmail.com
Message-ID: <1106314678.400005.255680@f14g2000cwb.googlegroups.com>
Source record: 20845

I am experimenting making a j pole out of 1/2 inch conduit. What I am thinking of doing is making it like a "u" in that each piece, the radiator, stub and shorting bar are cut at 45 degree angles and welded togther. I have the dimensions using the 1/2 inch copper. How do i measure each pieces "length"? I mean in the copper plan they use t fittings and measure the radiator length starting incide the t fitting where it is lower than the shorting bar.

My ides was to just measure the end of the angled piece where I cut it to the top, but not sure if this is right. What do you think?

Also, since an antenna constructed this way will not have an "extended leg" to mount to a mast, would it be acceptable to mount the shorted horizontal section to the mast? Will this cause problems?
Any help is appreciated. I hope to work on this tomorrow.

Where in Kentucky are you?

I have to be honest not been all that impressed by the coverage of the
Nashville Skywarn repeaters. But I don't have a very high UHF antenna.
I'd think if you could get something 25-30 feet in the air you ought
to be able to hear at least one of them reasonably well. Assuming you
aren't any further north than Russellville or Hopkinsville.

It's true that 'regular old PICs' are pretty slow, but for a low speed
(couple thousand bits per second) FSK modem, a processor with a MIP or so
could do the job using the 'cheap and sleazy' approach I outlined.

Ubicom does has some PIC clones that run at >=50MIPS, although I'm not sure
if they have hardware multipliers. The TI MSP430 line of microcontrollers
have models that, while they're running at some tens of MIPS, have a
slightly weird but completely workable hardware multiplier/accumulator and a
many channel ADC and duals DACs -- a very nice 'hacker's modem on a chip' if
I've ever seen one.

Hmm... I wonder if there's anyone doing QRP PSK31 work out there...

I'm trying to write a program (for my own education) that will transmit RTTY. I'm having some difficulty determining the exact format. From what I've observed from MMTTY, an idle keyboard has a 22ms space tone followed by a mark tone until the next space tone. I would have assumed that a standard letter/8bit transmit would last 196ms (22*8), but after recording it with a wav recorder and viewing it, it appears to be shorter (168ms or so, +/- 10). I'm not sure if the recorder is not accurate with timekeeping, or if I don't fully understand the format.

I would like to believe the standard format for a letter/8bit transmit is a start bit (space), data bits (marks/spaces), and two stop bits (space), *ALL* of which are 22ms long. Is this statement correct?
Thanks in advance,
Dave

No. It's a 5-bit code, plus start/stop bits. google for Baudot and you
can find a code chart.

The stop bit may be 1.0, 1.42 or 1.5 units long, with 1.42 being the
value based on the most common mechanical printers.

Hence, you will often see it called a 7.42 unit code.

As Jack pointed out, it is a five bit code. Even more interesting, it is a stateful code. There are two shift characters, LTRS and FIGS, which change the meaning of the codes that follow.

Years ago I was teaching a college assembly class and the Baudot code made for an interesting exercise <g>

I did something like this a few months ago on a 16F628. I was attempting to build a line-powered caller-id box. I got it real close, but could never quite get 100% copy on the data. I could get better than 99%, but even one bit error is one too many. Since I couldn't use an o-scope (no isolation transformer or probe set), I don't know for sure what the problem was. I do know one thing, it was the busiest PIC program I ever wrote. ;-) I really need a logic analyzer or DSO to debug this thing. It's possible (due to a recent project having issues that I resolved) that my bit errors were due solely to noise coming from the LCD. Sometimes it would get the data copy perfect, but most of the time there was 1 or 2 bit errors in the burst. Very occaisionally, you couldn't make anything out. :-(

I used the CCP module and TMR1 to measure the width of the top-half of the incoming sound. Based upon the width, I would toggle a PIC pin effectively ouputing a 1200 baud serial stream on that pin. That didn't look to good (0 vs 1 bit width distortion because of my technique), so I retimed the bits using another timer (TMR2). I then fed that pin to another pin that was a bit-banged serial receiver (RB0 int for start bit, tmr0 for the rest) that stuffed the received bytes into a circular queue. The main level code only looked for data to appear in the circular buffer and then printed it on an LCD. >90% of the time was spent in ISR routines. The whole thing consumed like 3mA. The PIC ran at 4Mhz and 5V using a Zener diode for regulation. IME, 2400 BAUD would not have been possible without using a higher speed crystal.

I have never tried sending modem tones from a PIC, but AIUI it's entirely possible.

Hi,

Further - the RTTY code is asynchronous where the stop bit may be any length over the standard 1.42 or 1.5 bit minimum. It is therefore almost standard practice to pass the key-strokes into a buffer and to output them from there so that the final result is almost synchronous. If this buffer should be emptied then some neutral character such as a 'letters shift' is continually output (called I think, 'diddling') to keep the circuit alive and to remove any DC component caused by a constant mark during 'hunt and peck' keying.

Don't forget to include the other common commercial standard of a 20ms bit-size (50 baud) in your program.

Cheers - Joe

627. Re: RTTY format

Newsgroup: rec.radio.amateur.homebrew

Source record: 20760

In both Baudot and ASCII an idle keyboard produces a constant MARK signal (loop current 'on' for a TTY machine), thus no signalling changes. In Baudot/RTTY
it's common practice however to periodically emit what is called a 'diddle' when
the keyboard is idle. Normally a LTRS character is used as the 'diddle'. This
helps the receiver stay better synchronized to transmitter. Different software
can be programmed to emit constant 'diddles' or to emit them about once a second.

No, an IF strip tends to mean including the detector. If he
meant "IF amplifier" he would have said that.

Even if the detector is not included, the modulation mode is needed to
define the solution. An FM strip will include limiter stages, which
you don't want for AM modes. Bandwidth selectivity is usually part of the IF
strip, and bandwidth depends on type of modulation, and indeed can vary
widely on the same type of mode.

The original poster sounds like he expects to find a module, and that's
not likely the case.

If someone needs an FM broadcast band IF strip, the obvious solution
is an FM broadcast receiver of some sort. A portable, a stereo receiver,
a car radio. There'll be the needed ceramic filter(s), and at this
point an IC that does the work. It won't be a module, but one could
either chop out the section, or trace it and then desolder the parts
and then rebuild it elsewhere.

Narrow deviation FM, an obvious solution is an existing two-way radio.
I've pulled actual modules out of older (and clunky) cellphones, but
they tend to have a first IF in the 45MHz range, or higher, and then
convert down to 455KHz. 49MHz superhet walkie talkies can supply

an IF strip for this, and most of them were 10.7MHz first IF and then 455KHz. But some dropped down to 455KHz. Old cordless phones operated at 49MHz, and again many use the same conversion scheme. The walkie talkies, and many of the cordless phones, that I've taken apart use one of the (now old) Motorola FM IF strip ICs, the included the conversion stage from 10.7MHz to 455KHz. Again, these won't be modules, but the walkie talkie boards are fairly small and one just needs to feed the signal in around the front end.

AM IF strips, the obvious solution is an AM broadcast radio. For narrower selectivity, a CB set will offer up narrower filters, and many will be double conversion with a 10.7MHz first IF and a 455KHz second IF.

CW, well there isn't likely to be anything floating around in consumer equipment. Either you live with wider bandwidth for AM, and then add a BFO, or you build from scratch.

Same with SSB. While some firms over the years have offered SSB IF strip modules, that's a rarity. And there's not much one can extract an IF strip from where the whole unit is not just useable to start with.

So for SSB and CW, one likely has to build from scratch.

But until we see a more detailed response, there really can't be an answer.

>Says IF strip...not detector...

Still makes a difference.

If you were to use a 455 if from say a Motrac RX for ssb you'd find
the lack of AGC (and easy way to do it) as it was designed to limit
would make for very poor results. Also an IF intended for SSB
use may not have enough gain and poor limiting for a FM RX use.

So the answer is that the intended use is important. Usually the
detector is part of the IF "strip" asssembly.

Looking for a nice HBR-16 or other receiver of the HBR line to continue some work I was doing 35 years ago. All leads appreciated.

Hi,

I'm quite comfortable impedance matching to large signal series equivalent impedances, when i get them in data sheets. No problem, even when i have to extrapolate a bit.

However, sometimes you only get scattering parameters. So we could use this formula:

Z11=((1+s11)*(1-s22)+s12*s21)/((1-s11) *(1-s22)-s12*s21)

Etcetera. But i don't wanna do vector math all the time. And i also don't wanna graph this gamma on the Smith chart by hand.

So i was wondering if there was a program out there, that will do this calculation for you?

Thanks in advance!

Dr. Slick

Not that I'm aware of, but it'd be trivial to code up in MatLab, MathCAD, or
even Excel if you wanted to...

Heck, even 'Windows Scripting,' which is really Visual BASIC, would work.
In the *NIX word, there's PERL, Rexx, etc...

642. JVC GZ-S3 camera connector

Hi,

A friend gave me a JVC GZ-S3 camera and I want to use it for ATV.

This camera has a 10-pin connector to its power supply and VCR.
Unfortunately, I don't have any of the original units, so I cannot do
anything with it.

I want to homebrew a power supply or adapt one of the units I already have
and use the video signal for my ATV xmitter.

Does someone have some data about the GZ-S3 connector wiring?

This camera is a nice unit, with expensive optics, it was state-of-the art
back in the '80s. I hate the idea of ripping it away for parts.

Here is a suggestion to provide terrific help with all kinds of math calculations. Mathcad is an excellent program that I have used for many years. It should be easy to find an older version such as 4.0 or 6.0 at very low cost which will do just about anything you can think of (I have version 12.0). This software is easy to get started with and can be learned more deeply with experience. Be sure to get the User Manual also. The equation that you illustrated is a piece of cake using Mathcad and complex S parameters. And the complex values of Z11 can be graphed on a polar or xy plot by the program over a wide frequency range.

Amazon.Com has a 6.0 version for $40 at this time (Sunday mornng). Be sure to get the User Manual.

Best method is to cut the length slightly over, then test on an SWR
meter, and trim a little at a time to optimize.

Different materials, different wall thickness, and different diameter
will all affect the apparent electrical length.

Happy trails,
Gary (net.yogi.bear)

Mathcad is a nice - but EXPENSIVE - computer program.

For conversion of S Parameters into any other form, a simple
handheld pocket-size scientific calculator would seem a better
investment. The Hewlett-Packard Model 33 calculator cost less
than $100 and can do complex quantity calculations (add,
subtract, multiply, divide, some transcendental functions) as
easily as single-quantity (scalar) calculations...and with a choice
of notation of fixed-point, scientific, or engineering exponent
formats. It is very useful for simpler calculations and the internal
battery lasts a long time thanks to internal CMOS electronics.
[my older HP 32S II has been going along on the original batteries
for nearly five years now] Since it is programmable, the 32 or
33 models can do formulas and a host of other pre-programmed
functions.

HP's marketing strategy for calculators seems to be sales
through its website or, possibly, if in-stock, at Staples, CompUSA,
Best Buy, or Wal-Mart. Easy enough to order on-line via -

www.hpshopping.com

Click on "hand-helds and calculators." On-line price for the 33s
is $50. The simpler, algebraic notation 30s is only $15, but that
one cannot handle complex quantities directly.

Greetings

In looking through my junk? box, I have found a number of crystal transmitter strips that I had collected over the 70's with plans to put various projects to practical use...

Unfortunately, time has a way changing ones directions in life...

I now find myself with these transmitter strips and would like to turn them into useful variable frequency transmitters. I also have one or two receiver strips using crystals.

When I see the police and other portable radio users, I often wonder how they get several frequencies in their handhelds. I also suspect that the various services, like police, ambulance, etc, have one handheld board and they have similar chips which are program for their particular bands or channels in mind...

I am looking through search engines, like google, but I wonder if anyone reading this might know of a company which produces rf synthesizer chips in particular that I could take a look at...

May I ask, first, what components, for your power supply, do you currently
have...
I gather you have the transformer.. what other components do you have...

I gather the transformer is 32 volts across the full secondary, with a
center tap??

Larry

There are a number of synthesizer chips ... probably the most popular for amateur use are those from Analog Devices. There are a large number of projects using the AD9850, which is kind of long in the tooth now, but still it works quite well for HF. It's main downside is that it needs a high frequency oscillator, and package crystal oscillators in the 100 to 120 MHz range tend to be kind of power hungry.

Check out http://www.amqrp.org and look at the DDS daughter card. It is about the simplest way to apply one of these. The daughter card provides pretty much the minimum you need to use a 9850. There are lots of other projects out there, including a couple of boards from Far Circuits, but most of them presume that you want to do something specific. The daughtercard has the basics and nothing more. If you basically want a VFO, there is a Far Circuits board that is pretty much the same as the DDS Daughtercard but adds a PIC, encoder and LCD to make a complete DC-30MHz VFO. AmQRP also has an IQ-VFO project currently that, I think, uses a 9854.

TI also has some nice synthesizers. Look into the TRF4400/4900 and also their TRF2050/51/52. They are cheaper than the AD parts, but AD is easy with samples. In fact, they make it pretty hard to buy one or two of their chips. Seems like they would rather give them away. The TI chips are generally UHF parts, but with a prescaler they can be used down in the HF range. The 4x00 parts are called "transmitters" but they are nothing more than DDS chips with a little more power out.

..

$40 for a program as powerful and multi-faceted as Mathcad 6.0 seems to me
to be quite a bargain and a gateway to a whole world of applied mathematics.

654. 2m VCO?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-01-24 00:10:08 UTC
From: James Bond <justmereally@hotmail.com>
Message-ID: <ct1ed0qnv1@sparta.btinternet.com>
Source record: 20786

i'm after a circuit for a 2m VCO.

basically i'm planning to homebrew a kind of tracking generator, where I can sweep across 2m to look at filter shapes, etc.

my plan is to sweep, using a vco, across 2m using a sawtooth waveform. this waveform will also be amplified and fed to an oscilliscope, to give me a horizontal sweep.

the output from the filter will then be fed to a RF millivoltmeter circuit (again, anyone got any good circuits?) and this will then be fed into a logarithmic converter then be put onto the Y deflection, to give me amplitude.

calibration will be by putting the system into "manual" mode and connecting to a frequency counter, then sweeping up and down until get specific frequency, then the x-centering be used to set this on a known point.

basically anything that having say 1-6V in giving a 140 to 150mhz sweep would be grand, then i can play with amplifiers to get it just as i want.

thanks all!

dr. x

Check out this circuit:

http://www.edn.com/archives/1998/111998/pdfs/23DI2294.pdf

It will easily tune an octave with just a few volts of tuning voltage.

656. Homebrew 3kV Power Supply

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-01-24 01:39:41 UTC
From: Jason Dugas <kb5urq@hotmail.com>
Message-ID: <10v8kep4ais1317@corp.supernews.com>
Source record: 20788

I recently got a high voltage transformer that I'm going to use to build a HV power supply for some future homebrew tube amps.

I'm curious if I'll need a high voltage voltmeter? I'm new to the high voltage world and so need some guidance or 'tips' in building HV circuits. I have already consulted the ARRL Handbook for all of the safety precautions, so I'm not so much looking for that sort of information, as I am practical tips in putting together the circuit and having some sort of meter to use in order to check various voltages throughout the circuit & on the output.

If I do need a voltmeter capable of measuring kV level voltages, what brands/models should I be looking for? If not, what equipment will I need?

Thanks,

Jason

657. detector diode conduction question

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-01-24 01:47:29 UTC
From: hexter@blazenet.net
Message-ID: <10v8kthpu9flm6e@corp.supernews.com>
Source record: 20789

Hello all,

I want to try to detect signal levels of 50mv to 200mv peak to peak. I need a passive circuit with no amplifiers, and I will be feeding a DVM with .01v resolution. The problem I am having is that a 1N34 will not conduct very well at these low levels. Is there a more suitable diode? Can you give me a part number, or a simple way to get just one or two of these diodes? What the diode is looking at is a 50 ohm port on a 30 to 60 mhz I.F. chassis.

Thank you for your time.

Another way to provide cal information is with a comb generator. Add a
controlled amount of this to your detector input and you get blips on the screen
at comb spacings. Obviously have this switchable.

>basically anything that having say 1-6V in giving a 140 to 150mhz sweep

Pinch the Tx VCO out of a highband mobile.

Thanks Bob, that would be excellent.

As i understand the Z11 formula
i stated, you will still get a vector
solution, so in essence the Z11 will
be a gamma reflection coefficient, or magnitude
(from 0 to 1) with an angle. So on top of that, you
will need to convert this gamma to
the complex series equivalent impedance,
which you can do graphically on the Smith, or

by using:

Gamma(Z11) = (ZL-Zo) / (ZL+Zo)

And letting Zo=characteristic impedance (assume
real! Usually 50 ohms), and then solving for ZL.

Well, i've never used Excel for vector algebra.

Could you throw something together on Excel, and send
me the file, so i know what you mean? If you could,
include the bi-linear transformation:

As i understand the Z11 formula
i stated, you will still get a vector
solution, so in essence the Z11 will
be a gamma reflection coefficient, or magnitude
(from 0 to 1) with an angle. So on top of that, you

Source record: 20793

Z11 is the complex input impedance of a two-port network that has an
open-circuit at the output port. That is, the output current is zero.

v1=Z11* i1 + Z12 * i2
v2=Z21* i1 + Z22 * i2

Z11= v1 / i1 when i2=0
Z22= v2 / i2 when i1=0
Z12= v1 / i2 when i1=0
Z21= v2 / i1 when i2=0

Z11 should be confused with S11, which is the reflection coefficient at the
input port.

S11=[(Z11-1)(Z22+1)-Z12*Z21]
/ [(Z11+1)(Z22+1)-Z12*Z21]

That's a good program, and there is tons of
stuff there.

But i'm not certain I can get large
signal impedances out of it. I mean,
when they give large signal impedances on
a data sheet, it's usually done by matching
the input and output on the bench, with
cut-and-try techniques, and then removing
the DUT, and using a VNA to measure the
what the transistor "sees" on both sides,
and then taking the conjugate of this, and
calling this the large signal impedance.
Matching to these usually gives you
good results.

How close Z11=((1+s11)*(1-s22)+s12*s21)/((1-s11)
*(1-s22)-s12*s21) will be to the stated large signal
impedances after you convert
it to a series equivalent impedance on the Smith
chart, I don't really know. It won't surpise me
if it doesn't come too close, as the s-parameters
are small signal.

Message-ID: <3Q_Id.25241$OF5.16530@attbi_s52>
Source record: 20796

Corrections to my previous: input:

In place of Z11, Z12, Z21, Z22 use
Z11/Z0, Z12/Z0, Z21/Z0 and Z22/Z0

I was not careful enough (as usual).

With these corrections :

S11=[(Z11-Z0)(Z22+Z0)-Z12 Z21]
/ [(Z11+Z0)(Z22+Z0)-Z12 Z21]

Now I have it right. As before, Z11 and S11 are not the same thing. But if the product Z21Z12 is very small, as in certain uni-directional amplifier circuits, then

S11 = approximately [Z11-Z0] / [Z11+Z0]
which is the familiar Gamma.

Reference: Gonzalez "Microwave Amplifiers" Second
Edition, page 62.

Note:

In the above formula Z11 should be replaced by
Z11 / Z0. In other words Z11 is "normalized" with respect to Z0 in this
formula. See the Gonzalez reference.

In a "normalized" Smith chart Z0=1.0.

It's certainly nowhere near as clean as, e.g., Matlab or MathCAD, but it can certainly do it. Look up the 'COMPLEX' function; it'll tell you you need to install the 'Analysis ToolPak add-in' and under 'see also' point you to the functions you'll need (e.g., IMSUM for complex arithmetic, etc.)

Right, or... just a regular old complex number. You can use IMABS and IMARGUMENT to obtain the maginutde and angle of your complex number.

You're correct according to Pozar.

I'm gonna assume that this was just a
typo on Gottlieb's part (pg.131, Practical
RF power Design Tech.), and what he really
meant to type was lowercase "z11", to show
it was normalized. (I have a feeling Gottlieb
just copied this out of another book, just like
i copied it from him! heheh...)

But you bring up a good point:
I might be barking up the wrong tree here if
Z11 or z11 is defined as the input impedance
when port 2 is open circuited.
This shouldn't be the same as the large
signal input impedance, when the output is
approximately conjugately matched.

Deliberate mis-representation of what you said I posted
having been corrected; thank-you. It is this....

Top-posting is preferable to bottom-posting because
you get to see the new material without having first
to page down through tedious tracts of material that
you would otherwise have had to read before (frequently
several times)

If the output is terminated with a 50 ohm pure resistance load then S11 is the complex input reflection coefficient, 0 to 1.0. In an active circuit (amplifier or oscillator) S11 can be outside these limits due to positive internal DUT feedback.

Another method would be to transform the 50 ohm source impedance to
something higher before applying it to the detector. Each quadrupling of the
source impedance will double the RF voltage. This could be done with an RF
transformer, or a loosely coupled resonant tank circuit.

I'd add a caveat that when dropping down from
the high voltage, do it with a chain of series resistors,
each physically separated from its neighbour so that you
don't get flash-over. i.e., restrict the voltage over each resistor to
less than a couple of hundred.

I bought an ALinco DR 590 dual band amature radio at a hamfest. It is a mobile. Got it home, hooked it up, everything on the display lit up. I mean everything, even things that were not supposed to. The frequency number has stange lines in it. It was not usable.

Came back later and it started working fine even made soem contacts with it. Used it for about 20 minutes, no problem. Put the radio away inside.

Hooked it up last night to try out some antennas and it did the same thing. I played with it for an hour to no avail. Took it inside and took it part way apart, did not see anything, maybe soem pinch wires to the display but could not tell. Put it back togther. Hooked it up and it worked fine. left it in the garage last night. Hooked it back up this morning before going to work. It worked fine.
Am I crazy? What could this be?

Carbon composition resistors are not linear above a few hundred volts.
There are resistors specifically designed for this purpose.

You can also purchase Fluke, Heath or Eico HV probe on EBay for about $20.

If you are building a high voltage supply I would strongly urge you to take
a look at some of the supplies manufactured by Collins, Heath, Hallicraftes,
Drake etc. in the 1960's and 1970's -- there are several layers of
protection, failsafe and redundancy in all the power supplies for their
amplifier so that the operator wouldn't fry themselves.

My Dr 590 has two connectors one for vhf one for uhf. WHile hooking an antenna up the connector actually came out of the vhf. I looked but could not see any wires in there. I put it back in and at least according to my swr it was putting out wattage.

How do these things go on and do I need to do something different? DOes it need to be soldered?

For peak voltage under 100 mV, tunnel diodes produce more output than
other diodes, but are hard to find.

That's news to me! Would you care to expand on it?

If one could look at a carbon atom in isolation, how is
the conduction mechanism changed by the size of the
applied electric field?

Hi,

In reply to your first posting, I must have been half asleep when I suggested AppCAD as a solution to your problem because large signal impedances and s-parameters are like 'chalk and cheese'. There isn't (as far as I know) a simple way to translate one into the other because of the intrinsic non-linearity of DUT parameters with respect to operating point and drive level. On the web you should find papers dealing with this problem but the parameters generated by the methods employed are not just a simple mapping from S to Z.

Cheers - Joe

Some items of test equipment have a display 'test mode' where every digit and LED/LCD segment are switched on either in sequence or at the same time as a function check. I have three items of test equipment that do just that on demand, so it could be that your rig was simply strutting its stuff.

As for the socket coming away, again it may be meant to. Perhaps the terminal plugs into the assembly just behind it.

Cheers - Joe

If this was a "test" mode then why did it stay in test mode? The radio
was completly not usable.

You said something to the effect of having it in your garage. Not sure if heated or not, but the temperature changes could be doing this - if wide in nature - cold to warm - etc. Could be a bad solder joint. Display may be going flaky. You bought it used, who knows what ales it. A copy of the owners manual if you don't have one - would be a good start.

I have a JVC GX-S9U camera that has a 10 pin connector. The wiring for
it is:

1 - video
2 - video shield
3 - ????
4 - ground (possibly for the remote control or the channel 2 audio shield)
5 - channel 2 (right) audio (camera has a jack for a second mike)
6 - remote control (pause)
7 - channel 1 (left) audio (built-in mike)
8 - audio shield
9 - ground (for +12 volts)
10 - +12 volts

I would expect yours to be wired the same but you never know.
Measure between pins 4 and 9 to see if they are shorted together.

This is true. Especially if you are dealing with
highly non-linear, saturated PAs and such.

Ok, but let's say i wanna design a linear, class A PA, and
i need to know Zin and Zout, so i know what to
conjugately match too. I should be able to do this
with ADS using a *.s2p file, but i haven't figured
out how to do this yet! There should be a freeware
program out there...

> How do you have your
> antenna wire coming into your shack?

About the best method would be to replace a small window with a metal panel. Earth (ground) the panel well and fit back-to-back chassis-mount connectors. You can stuff in more connectors than you need, for future use.

Ground the shack internal equipment to the same panel, especially if you have high antennas/masts or long HF antennas. A good ground can save a lot of tears if you ever have a lightning strike. Of course, you can never protect against a direct strike, but you can protect against an indorect strike.

With this method you will reduce the risk of indirect lightning damage as well have a connection panel on the inside so you can swap plugs around easily. You can easily unplug equipment in stormy weather.

Don't forget to add a "drip loop" to all external cables terminated to the panel, or rain-water could be guided by cables to the face of the panel.

Do not be tempted to use a simple perspex, or other insulated panel. You could bring static into the shack, or even feed volts out (non-grouded equipment - mains leakage), which can give you a bit of a shock when working on antennas and you are well grounded :-(.

You can use "Zero-bias schotky diodes" for detecting small signals, but you can also pass a small bias current through an ordinary diode to overcome the forward conduction voltage.

I am extremely interested in this article. I signed up with EDN over 12 hours ago, but the only thing I've gotten is that my "subscription is processing", whatever that means. So far it means that I don't have the required password to access the archive. :-(

Since the subscription is free, and I've already tried completing it, can someone please e-mail me this file?

The paint on the resitors is not a perfect insulator - it breaks down
as the voltage increases. This is why there are high voltage resistors.
Not rocket science exactly.

And if you are going to stuff around with HV, make sure there is
someone aound who can do CPR when you fry yourself......

I am so confused about how to properly ground a system. I will have a two meter and a 440 on the roof of my house. I will run the coax down to my sofit vents or whatever they are called and run the coax inside the vents to my shack. Behind the wall where my rquipment will be is a storage space that I can acess. (This is a finished attic). I will be using a mobile radio that has two antenna outputs, one for 2 meter and one for 440.

How do I ground the radio and does it need it? Should the coax itself be grounded and how? Do I have to purchase one of those surge things that screws into the coax?

Any advice is appreciated!

I have an older ALinco DR 590 radio with two antenna outputs, one for vhf and one for uhf.

What is the cheapest way to be able to use on dual coverage antenna? Can I use a satellite diplexer, can I make one? ANy advice is appreciated!

I don't buy the paint theory much . . . The original answer specified
a few hundred volts per resistor and that isn't exactly high voltage .
. . The common radio shack flame proof 1/2 or 1 watt sizes would be
my choice for ruggedness.

A long time ago I repaired vacuum tube TV sets. I'd find an
occasional high value resistor with a short in it, or very lower than
tolerance reading. These were usually high value resisters with
relatively low current, across higher voltages ~400-500 and up.

When I asked about it, I was told that when resistors dropped high
voltage DC (these were carbon comp 10%'rs - back then) for long
periods of time, the copper in the leads migrated into the carbon and
lowered the resistance. In the case of something like a screen
resistor - it could go for quite some time before it caused a
noticeable problem - or at least severe enough for the customer to
have the set looked at.

It was a frequent problem in the old tube type CB transmitter output
stages - so RF may have accelerated the problem?

I have an old "boat anchor" style variable HV supply I picked up at a
ham fest. It has a 100 ua meter on the front measuring the 1 KV
output. The dropping resistor is part of the bleeder string - six one
watt resistors.

Stay safe. If it can kill you - respect it.

I saw one of my colleagues take a hit from an ancient high power Navy AM transmitter. The thing had every safety device imaginable on it (in fact the safety interlocks were the most troublesome part of the devices). He followed protocol and picked up the shorting bar in the compartment and put it to the HV caps - no arc so he assumed it was safe (it had crowbar relays that short the supply when the covers are removed, the shorting bar was extra safety).

He took it from his hand on the shorting bar (the ground was broken). A spark shot from his ass to the scope cart behind him. He suffered no physical damage - but he went into shock and wouldn't go near that transmitter again.

SemiConductor Theory

(c) 1997 by Gareth Alun Evans

A transistor is rather like the human alimentary canal, after the
typical USA diet of burgers and chips; - it constipates, as do
semiconductor diodes with no applied bias - the available holes get
filled in and nothing can move.
The base current is like a small application of laxative; some of
the constipation passes through, until the effect of the laxative wears
off. The total throughput depends upon the Mobility. By applying a
continuous feed of laxative, then a continuous current passes through.
Applying too much laxative results in saturation - ie, there is a limit
to the maximum throughput, depending on the external circuit; in this
case, the maximum rate at which you can feed in the burgers at one end.
(If you are a customer of MacDonalds's, here in Chippenham, Wiltshire,
UK then this rate is very low - I have been there twice, and both times,
the service was *APPALLING*.)
The difference between PNP and NPN is the direction. In the old
days, PNP was used, whereby one injected from the rear end, using a sort
of huge syringe - hence PNP - "Put-in Near Poo". More recently NPN is
more common, where the laxative is entered via a carrier of some sort,
usually chocolate and so we have NPN - "Now Pleasant Nutrient".
Despite the adverse effects, the USA diet of burgers and chips
carries on, and recourse has to be made once again to the chocolate. Now
the ratio of the carriers of the constipation, the burgers and chips, is
much higher than that of the chocolate. Thus they are referred to as the

Majority Carriers and the Minority Carriers. If you indulge too much, you find that the vendor will provide you with a paper bag, known as an Excess Carrier.
More recently, there are problems with impurities and you find that the opposite effect occurs. You have no time to reach home before diarrhoea takes over. You have no option but to stop the car and nip over a gate into a field. Hence the Field Effect Transistor. This time you have to inject something to STOP the flow. Now, assuming that there was a certain control over events; nothing happened until the Gate was encountered, you then became the Source of flow, and the field itself acted as the Drain. What was originally dirt, became grass, was consumed by the Cow, you ate it as a burger, and it has now returned to the topsoil, an effect known in the trade as Surface Recombination.
(Incidentally, did you know that Diarrhoea is hereditary? Apparently it runs in the jeans.)
Some of the impurities accumulate in your rear end, and no matter how valiently you try, you cannot rid yourself of them. Hence In-de-Bum is known as a Try-Valient Impurity. In the same way, Arse-nic, well known for its ill-effects and accumulation in the body tissues is known as a Pent-Up-Valient Impurity.

Where can I get a detailed description of AMTOR-B's protocol? I'm not looking for just basics, but rather enough information I could actually write a program to decode and encode an AMTOR-B transmission. I've done several searches on google (and other sites), but haven't found anything that really covers the low-level details.
Thanks in advance!
Dave

For a new basement installation, I drilled an approximate 2-inch-diameter hole through the sill (would have just drilled through both walls if I had been on a higher floor) and inserted a 2-inch piece of PVC pipe with a downward-pointing elbow on the outside end; lots of coax cables will fit through the PVC pipe.

I had a Ufer ground installed when the basement was built, and all my equipment is grounded to that inside the basement. My tower is also connected to that Ufer ground and to a ring-ground that goes around the outside of the basement at foundation level.

Regarding using

>... [through-the-wall] PVC pipe with a downward-pointing elbow
>on the outside end [for running cables into the house]....

I should add that, after threading coax cables through the pipe, I stuff
either fiberglas or steel wool into any left-over holes between/around
the cables in the pipe to keep critters out and heat in.

==========
Earthing any antenna does not protect against a lightning strike.
The best way to protect equipment attached to any antenna is to disconnect the feeder near the radio equipment , keeping the feeder metal connections away from any other metal.

When I go away from home expecting 'static' activity and lightning ,I always disconnect the antenna feeders and 'park' the connectors inside a plastic box

However ,earthing an antenna does help preventing static charge build-up .
Hence following a feeder disconnect ,before reconnecting it to radio equipment , I briefly 'touch' the feeder connection(s) to earth.
My double ZEPP or Doublet wire dipole with balanced ribbon feeder has 2 ea composite 47 kOhms resistor at the matching unit (tuner if you wish) connected to chassis/earth.

dave.harper@gmail.com writes:

> Where can I get a detailed description of AMTOR-B's protocol?

The 2005 ARRL Handbook, p. 9-19, in the bibliography for the section on AMTOR, contains the following:

CCIR recommendation 476-3, "Direct-Printing Telegraph Equipment in the Maritime Mobile Service." Reprint available from ARRL Headquarters as part of the Proceedings of the Third ARRL Amateur Radio Computer Networking Conference.

With that hint, typing 'CCIR 476-3' into a search engine might turn up a copy of the official definition online somewhere. "SITOR-B" or "NAVTEX" might be other good search terms to try, since SITOR is what the protocol is called in the maritime mobile service, and NAVTEX is the service that the US Coast Guard provides using SITOR.

I realize that you want to write your own program, rather than copy or use an existing one, but you might find the source code of hfterm instructive. http://hfterm.sourceforge.net. It's a Linux program that implements AMTOR, PACTOR, GTOR, and some other digital modes.

It should be grounded for lightening (for RF there is no need). Also
A spark gap or similar device should be on the coax as the fed element
is not grounded (all the arrow OSJs). It is sufficient to bond its
mounting to the metal mast (or tower) and the mast to the earth
ground.

An 1N270 germanium diode is very good for the purpose - up to at least
1GHz. If linearity is interesting, it is easy to construct network to
keep accuracy withing 10% http://home.online.no/~la8ak/m2.htm

If you have a fairly strong local broadcast station an auxiliary diode receiver will create the DC bias voltage for the diode in your application. That detector and your application can operate simultaneously.

Find a copy of an older Radio Amateurs Handbook in the pre 1980 circa
and there is more coverage on the subject there.

However, The basic idea is a spark gap from the center conductor to
shield (and ground). At HF to interrupt the shield of the coax is
trivial and of minimal effect of the transmission like
characteristics. As one reaches the VHF/UHF range higher it becomes
significant to critical as even small changes in the coax and
interconnects are measurable at UHF. So as frequency goes up the
mechanical shapes and connectors are important and less readily home
brewed without a lathe and other tools.

Besides there are excellent products with known characteristice
available for reasonable prices from I.C.E., PolyPhaser and others.

Ah not quite. The coax shold be grounded also. See the PolyPhaser site about lightining protection. It makes little difference as to the type of antenna from a practical standpoint of lightining protection.

The key issue around lightining is what are best described as sneak paths. Due to the imense current (in excess of 10,000 Amps) even a fraction of an ohm resistance difference between the strike point and ground allows a significant voltage to develope (10,000A* 0.1ohm=1000V). I might add that in that example a resistance of 0.1 ohm is likely an unrealisticly low number. Also since it's a pulse of energy it induces currents just like the magnetic field in a transformer or generator so even nearby conductive objects can have currents and voltages induced on them. This gives rise to those sneak paths. So this means if you want tp prevent a lightining hit (or near miss!) from finding its way into the shack you will have to pay attention to details. This includes phone and power lines. I've not gone into a lot of explanation here and I've glossed over much as well so please research it deeper.

As side note: I've been hear missed three times and all three times the greatest destruction came via the phone lines! I've lost phones, computers because the spike was propagated from the phone to the computer that was connected to it via an external modem. This can give an idea of sneak paths. To truly effect a Lightining protection plan you have to address the antenna system (antenna, tower, feedlines), the power system (what the radio runs off of) and the phone system (you may have a computer with DSL, cable modem or Phone modem connected to the radio). It's not difficult but, attention to small details and following known guidelines is important. Oh and don't scrimp, a good system is cheap compared to damaged electronis or a house fire.

There really should be no problem detecting such large signals with an unbiased diode. I use Agilent zero-bias Schottky detector diodes, but your 1N34 should work about as well. The key is realizing that you simply don't get much output from the diode detector at low input levels, but I'm quite able to detect signals below 100uV -- yes, 100 microvolts -- with mine. Your signals are actually quite large, and start to get into a transition region between response at low signal levels, where the output voltage is proportional to input power level (into a resistive load), and response at high signal levels, where the output voltage is proportional to the input voltage. So you may need to calibrate at several points. Be aware, too, that the response depends on temperature. I believe you will be able to find some application notes on the Agilent web site in the components section.

Although there are some really nice RF level detector ICs now from places like Analog Devices and Linear Technology, a simple passive diode detector can still be useful in many cases.

Cheers,
Tom

Source record: 20713

Hi folks,

I have several "radio controlled" clocks in the house and all but one won't receive WWVB tranismissions. They work OK but they are below ground. I was wondering if I can buy a repeater, build a repeater, or build a transmitter. I'm thinking I could put a repeater where the signal is always strong and rebroadcast the signal a little stronger so that the entire house is covered.

Another thought I had was a transmitter. All the PC's in my house use Internet time servers. I can easily build an interface to create the WWVB time code from PC time. If I had a transmitter, I could broadcast throughout the house.

Can anyone help? By the way, I've been working in electronics since the mid-70's but my knowledge of RF is limited to tuning the radio in my car - and that stuff is pre-programmed!

Thanks in advance.

Vic

Hey, something I can answer intelligently! :-)

In your attic, make a resonant loop of wire as big as possible (think magnetic loop design without the feed coupler - lotsa programs out there to design one). That will enhance the field throughout your house.

I've tested and used them for AM radio and cellular phones with success.

You'll need a radio receiver in your basement (or wherever "undergound" is in your home and someone to confirm peak strength as you tune. FRS talkies come in handy for this ;-)

Some libraries will arrange inter-library loans at no cost.

Here, at the Tempe Public Library, each patron may have
up to 3 such requests active at a time.

Sometimes, there is a small charge if they have to go out
of state (Arizona) or whatever.

734. WR-90 X-Band aperature attenuator question??

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-01-28 05:26:09 UTC
From: hexter@blazenet.net
Message-ID: <10vjj7hjn5lk224@corp.supernews.com>
Source record: 20717

Hi folks,

I needed to produce some referance power levels that were 'down' from my calibrated 0DbM generator. (It's output power is auto leveled, and non-adjustable) 9445mhz, center of one of the maritine radar bands.

I built two little aperature plates that look like a waveguide cover, but have a hole drilled in the exact center. A .185" hole provides about 45db of reduction, and a .310" hole provides about 25db of reduction.

There are some differances of exact gain reduction depending on where in the waveguide system I place these plates. (Close to source, or close to receiver) Perhaps up to about 3 db difference, not a big worry for me.

Do the numbers sound correct? Should I have attenuated in a differant way? Like perhaps a slot, instead of a round hole??

If I want to make some more of these plates, is there some math to help me predict the size of the hole for 10db?

Thanks for your help and comments. I am exploring some new areas here.

You might google for "waveguide vane attenuator". That is the device
used to measure fade margin on microwave links. A company called ARRA
makes them, so did HP at one time. There is a lossy vane which rotates
into the waveguide, turned by a calibrated knob and scale. Might be
worth your while to check e-bay to see if you can find exactly what you
want. Also some old microwave radios had these attached to the output
waveguide. Of course you need to find X-band.

Some of the older Tek 400 series scopes had an amplified output from
one vertical input channel. This could be left connected to a
frequency counter if you wanted.

What kind of scope do you have? Have you checked to see if it has such
an output?

==========
There are also PL259 connectors with internal thread to suit RG58 coax
directly .
For fitting coax strip a short length of sheath ,fold braid back over
sheath ,strip polyethylene to say 1mm from braid end ,screw coax end covered
with braid into connector ,solder centre conductor to connector tip.
I prefer this type of connector over a PL259 for 10mm (3/8inch) coax with a
screwed adaptor.

I use RG58 coax for short patch leads only.

JM, I also have a popular mega website on Amateur Radio and receive numerous questions.
I answer those that I can and like you refer them to the news groups.

The greater majority of folks do not know how to use news groups or are even aware of their existence.

So I refer them to URL:
http://www.blackviper.com/Articles/WWW/usenet/how2newsOE6_01.htm

I also have instructions for accessing the NG's on my website.

Many come back with "I have to subscribe, so declined"
As you and I know it is not a subscription per se, only setting up your browser.
One has to subscribe to a mail list or reflector - but not the NG's.
Seems folks avoid anything that involves a setup or registration.

Others come back to me stating that when they viewed the NG's -- they were so full of junk and obscenities that they wouldn't return.

Sad as many experts frequent the NG's and they can be a very valuable resource.

In several instances, I posted queries for them and often someone would reply.

--
Caveat Lector --- Anon by necessity on the NG's -- thus avoiding your problem of "somebody gets
very insulted and tell me strange things"

Hi,

> Have proposed they try newsgroups which I listed, but somebody gets
> very insulted and tell me strange things, it seems that only a smaller
> fraction of those who access has any idea about newsgroups and how to
> access them

There are two main reasons I think. Firstly that newsreaders aren't generally integrated into browsers so that many people don't know that these groups exist. And secondly, posting to a newsgroup exposes you to public view and thus possible criticism which is never easy to handle even with the thickest of skins.

Consider the postings which start off "I don't know much about electronics but..." which is unnecessary as most people are only to happy to help if they can. Or those from the abusive ones in our midst who hide behind a "nom de guerre" and add little to the sum-total of human knowledge.

A great web site you have by the way.

Cheers - Joe

Thanks for the info, Gregg. In my original post I indicated that RF knowledge is very limited (FM does not mean frequency modulation to me). Your response was intelligent - my understanding is not.

I gather I can build a loop of wire that resonates at 60KHz, put it in my attic, and it will reradiate the signal. Does that sound right? Won't it have to be big - the wavelength at 60KHz is 5000 meters!

I did do a search on the Internet and found a lot of stuff about magnetic loop design but most of it appears to be connected to transmitters. Do you have good links I can review?

Thanks again for the reply!

Vic

<< I needed to produce some referance power levels that were 'down' from my calibrated 0DbM generator. (It's output power is auto leveled, and non-adjustable) 9445mhz, center of one of the maritine radar bands. >>

I've never worked in this band, but recall that some lower-frequency signal generators use a "waveguide beyond cutoff" attenuator. If you can find some waveguide sections designed for a sufficiently higher band, the attenuation will be proportional to their length.

This doesn't address impedance mismatch, but neither does your method.

Ooops, in my first reply I missed that your DVM has only 0.01V
resolution. Wow! Even a 3.5 digit one at 2V FS resolves millivolts.
So to keep things passive, use an RF transformer to step up the voltage
to the detector diode(s). I trust your DVM has a high input
resistance, so the RF loading by the detector and its DVM load should
be quite small. You might be aided by using a voltage doubler scheme,
in addition to the transformer stepup.

Cheers,
Tom

> my attic, and it will reradiate the signal. Does that sound right?
> Won't it have to be big - the wavelength at 60KHz is 5000 meters!

It will create a resonant field and concentrate the 60KHz energy in your
house.

You can use a multi-turn loop. Square, 4-turns, maybe 2M per side and an
AM tuning capacitor.

> I did do a search on the Internet and found a lot of stuff about
> magnetic loop design but most of it appears to be connected to
> transmitters. Do you have good links I can review?

The program you want is called MLOOP31.EXE (exact filename). That will
help you find it easier. All you need to know is the physical dimensions
of the antenna, like 2M/side, 1cm spacing, etc., physical dimensions of
the wire (alarm wire is 1mm in diameter for example) and so on. Just
ignore the dimensions for the feedloop.

Tell ya what - when I reboot into Windows, I'll use my copy to make some
calculations of some dimensions for you :-)

But you might want a copy for yourself, 'cause it's a real neat proggie!

Come to think of it, it's redistributable freeware - I can post it on
ABSE (alt.binaries.schematics.electronic) tonight.

Source record: 20733

Some calcs for you Victor,

4-turn loop, 2M each side, seperated by 1cm. The following tuning
capacitance is required for 60 KHz:

1mm dia. wire: 60,180p
1.5 and 2mm dia. wire: 65,580p

That's an awful lot and the tuning will be only a few tens of Hz wide.

If you have the capacitors, go for it.

If not, maybe an active antenna for your underground receivers?

BTW - the program is posted to ABSE. It won't go down to 60KHz, but you
can scale 1MHz results accurately.

From: Victor Lick <aaa@bbb.com>
Message-ID: <yMudnRcccteyGGbcRVn-qQ@comcast.com>
Source record: 20736

Thanks for the numbers, Gregg. I managed to find the program as a ZIP file all over the Internet but everyone I downloaded wouldn't install.

The antenna you calculated is big, way too big to go in the attic. It was a cool idea though. Imagine giving people of a tour of my house. "...And up here we have the WWVB reradiating magnetic loop antenna with a resonant frequency of 60 KHz and a bandwidth of 56.2 Hz." I can hear them now, "Geez, Vic, you are a major geek."

Anyway, a 2M wide antenna is a bit big so I need to find another way. Active antennas won't do either. One clock sits on my desk in my office and the other one hangs on the wall. Antennas on those will have a very low wife acceptance factor.

Can I build a repeater? The receiving antenna in these clocks is small. Maybe a small low power transimitter with the same size antenna? Can I buy a repeater? Can I buy a transmitter?

Thanks for all your help on this,

Vic

The only problem I would have with doing it is what you have hinted at:
you do not have any evidence that the thing works! So definetely I would
find out first as you are attempting to, if the thing has ever been
constructed and does it work properly. Secondly, unless you have a very
good box of parts getting all the bits and pieces could nickle and dime
you to death. That is one advantage of going out and buying a Elecraft K2
kit instead!

That's the problem with second hand radios.....if yours is having
that problem. Most of the stuff I've seen lately has been junk. It seems
that many of the hamfest folks (not all of them) are following eBay's
tradition. At the last hamfest I attended (Radio Expo), I ended up with a
100% average.....I had to repair everything. Of course,
everything was misrepresented as "working fine". On the subject of your
radio, I have purchased radios over the years that do hold their memory, but
they did have some of those weird problems. Replacing the backup battery
cured the problem. And then, there is the other side of the
coin.....this is the one where somebody replaces the backup battery
and subjects the uP to ESD. End of story, unless you are adept at replacing
quad flat-pack ICs (not too hard, but you need the right technique). It also
helps if you have a stereo microscope when replacing one of these devices.

For a wall clock, I would try adding a field concentrator antenna all
around the back edge of the clock, to put most of the field that
passes through that area, mostly through the clock's antenna. For a
small table clock, this approach is not so tenable, unless you can
paste it on the under side of the table, and produce the concentration
where you normally sit the clock.

but another case is that while normal attenuation may be 0.15dB/m for
a waveguide within the specified band, it may become 0.1dB/m below the
cutoff frequency, it seems that the lower limit is not for
attenuation, but for phase relationship, so it may be difficult to
predict phase along the cable and it is a question of narrowband
contra wideband applications

Oh, yes!

This reminds me of an old PopComm article, where someone re-wound a
ferrite loop antenna and tuned it as a concentrator. They are only 6"
long!

Here is my take on the likely problem with the radio. I have a Kenwood TM241a mobile radio that had a similar problem. It turns out that a LOT of them did. The connector from the main board to the display has problems in this unit. I took the unit apart, cleaned the connector, with DeOxit, and after reassembly, it works fine. Some people have written about using a soldering iron to beef up the connector pins on the circuit board. I suspect that this may be your problem. It is about a half hour job, if that.

Hope this helps!

I have found your statement to be very true indeed. I have learned so much from several of the N.G.'s that I post to. Learned a long time ago to use a bogus return address however. I hate being spammed, although I really don't mind being flamed, as everyone has an opinion, good, or bad. I have purchased some equipment from folks in the scuba newsgroup. They actually gave me business referances to check them out beforehand.

It amazes me how many of my 'techie' freinds have no clue about N.G.'s. Totally unaware! I thought newsgroups were around before www webpages. Yikes, showing my age. So much useful information to share, and so much bandwidth wasted on commercial marketing racketeers, and spammers. Personally, I think webcasting is a waste of bandwidth. I am living in the U.S.A., but when I desire to hear Utvarp Reykjavik, I sat down and built a 6AJ5 tube type low noise convertor for 15.770mhz, and feed it's output to a 1964 Pontiac car radio. That rig is hot! Listening to an Icelandic broadcast via webcasting would be like shooting my engineering talent in the foot.

Best wishes all, from a viking in the states.

According to the one reference I can lay my hands on at the moment
(MIT Rad Lab Report No.43, Feb. 1944), a round aperature in a W/G is
equivalent to a shunt inductance.

The reference gives the data in graphical form. I put a few data
points into Excel and let it solve for the normalized susceptance v.
iris diameter.

For WR-90 guide (0.4" x 0.9") at 9.445 GHz, the formula is:

-Y' ~ 0.2838 * (d/0.9) ^ -3.1635

Where Y' is the normalized susceptance and with the iris centered in
the W/G "d" is the iris diameter in inches.

The reference doesn't specify a thickness of the iris plate, but I
would assume it's for plates << lambda.

After writing the foregoing, I remembered Steve Adam's book,
"Microwave Theory and Applications" (I should have remembered it
sooner, he signed it for me).

He references H. Atwater's, "Introduction to Microwave Theory" for the
following equation:

Z/Zo = j (2 * pi * d^3) / (3 * a * b * lambda_g)

Where for WR-90:

Zo = W/G impedance
a = 0.9
b = 0.4
d = iris diameter in inches
lambda_g = guide wavelength.

Whether these two references give the same answer will be, as they say, left for an exercise for the reader.

What you're getting with these reactive elements is mismatch loss. If you want true loss in your W/G, you must introduce resistance.

Some suggestions -

A two-meter loop antenna isn't needed. You could try one the
size that I made to receive WWVB in southern California from
Fort Collins. That one is 58 1/2 turns of #14 solid electrical wire
wound over a wooden former to a maximum diameter of 33 inches
(83.8 cm). That size was dictated by a trap door to the small
attic in my house. An electrostatic shield made from aluminum
foil went over that, the whole bound together by jute twine which
was varnished several times to hold it together. A single piece
of 1" diameter PVC plumbing pipe provides support for hanging
from a beam and maintain circularity.

Measured loop inductance is about 5.7 mHy so the 60 KHz
resonating capacity should be about 1230 pFd. But, with
high distributed capacity (measured by two-frequency method)
of about 395 pFd, the required parallel capacity would be
about 840 pFd. Q, measured as delta-f between -3 db
points around resonance is about 44. That results in a
bandwidth of 1.3 KHz but that can be narrowed by tuned
amplifiers.

Note: Those are actual measurements, not textbook data.
Ordinary THHN type insulated solid electrical wire was used
to reduce cost (in a 500 foot roll that is cheaper than buying

enameled solid magnet wire).

Signal strength in volts is proportional to the number of turns
in the loop. At this location, roughly a kilomile from Fort Collins,
the induced voltage was about 400 uV. That is less than WWVB
reports of higher field levels at San Diego, a slight increase in
distance from Colorado. My location is hampered, perhaps, by
a mile-plus of 100-foot higher hills in the direction of WWVB.
Two manufactured radio clocks have been working just fine here
for four years. My attic is about at the same height as my
uphill neighbor's ground level.

I've got a differential input first-stage amplifier, J310 FETs as
source followers into an MC1350P differential video amplifier.
The loop connections are brought in by RG-59 TV cable with
about 210 pFd per cable. A two-gang variable at the WWVB
receiver tunes for peak. Differential input helps reduce some
common-mode noise pickup (such as from "high efficiency"
switcher power supply lamps).

My use is just to extract the 60 KHz WWVB carrier. That is
done by additional MC1350P stages, that IC effectively working
as a limiter at high input levels. Tuned amplifiers without
limiting will work fine to preserve the two-level AM time code.

It is very difficult to arrange a 60 KHz "repeater" without inducing
feedback. I would suggest using one or two lengths of cheap
75 Ohm TV cable from an attic location to the basement level.
Normal 20.5 pFd per foot RG-59 will hold fairly stable despite
temperature variations. A long length of coax, even 500 feet,
wouldn't matter much relative to the long wavelength of 60 KHz.
Two lengths into a differential input amplifier to reduce stray
pickup from appliances and lamps over a long run.

A wired amplified 60 KHz signal can be coupled inductively to
a radio clock with a turn or two (perhaps) around the case or
even capacitively. That would depend on the internals of the
radio clocks.

Trying to make an on-frequency wireless repeater is a setup for
feedback and oscillation unless there's lots of space between
pickup antenna and the repeater transmit antenna. Not
recommended but it might work if the pickup is in the attic and
repeater transmitter is in the basement with low power output.

There's no such thing as a passive amplifier. One might narrow
the effective beamwidth of an internal radio clock loopstick with
an external loopstick but, in all probability, just orienting the radio
clock itself would help.

Hi, I'm looking for a multimeter that will be
used 24/7 on DC and mA readings. Are there,
in your opinion/experience, any difference in
long-term durability between the Fluke 87
(series 80) and the Fluke 81438 multimeters?

775. Re: Any difference in durability of two models of Fluke multimeters?

I've had one of the Harbor Freight multimeters on a monitoring point 24/7 for six months and (except to change batteries) not a whimper. My students have bought somewhere on the order of 100-150 of them and as yet, not a casualty.

They are on sale for $2.99 right now.

Is this hard? I have an alinco DR 590 that is acting funny. Checked the battery and although it was keeping memory it showed less than a volt.

It is a BR 2032. Do these things come with the tabs already on the battery when you buy them?

Is this a "REPEAT" post? You've been asking the same questions for over 2 weeks now. As one other poster suggested, DO SOMETHING. For Christ's sakes, you keep asking the same questions in like 5 different news groups, and you've STILL not managed to get it in your head what they're trying to tell you.

Getting help on line is good. I and I'm sure tons of others don't mind helping, but for Christ's sakes - PUT IT TO ACTION.
If you can't figure it out by now, then get an ELMER near you to help out. Otherwise, you're going to be a hell of a lot worse off than you are now, and from the looks of things, that is pretty bad. In case you are clueless as to an Elmer, it is a person with experience who can show you up close. From the sounds of things, you SURE could use one.

Otherwise, I'm beginning to wonder if you're not either slightly mentally deficient or a troll. NO ONE asks the same questions over a couple weeks and gets answers and has to still ask the same questions.......

==========
Depending on the number of digits your readout needs to have , DVMs are nowadays very cheap .
Here in the UK a well known electronic components/gadgets chain store sells 3 digits multi-function DVMs (LCD display) for GBP 5.00 or US$ 7.00. Some time ago they sold these DVM as a promotion for GBP 3.00 or US$ 4.20 ,complete with 9V battery + leads and a soft plastic pouch. It is Mastech's model M-830B sold by Maplin
At that price 'long term durability' is no matter of concern.
BTW when comparing the reading of these low cost DVMs with a similar 'professional instrument ' the difference is at the most 2 of the least significant digit.
As a radioamateur (hobbyist) I feel these DVMs are fit for my purpose.

Yep, time to replace it.

> It is a BR 2032. Do these things come with the tabs already on the
> battery when you buy them?

I looked up the data sheet for a BR2032,
http://tinyurl.com/67puy

and it doesn't show tabs attached. If your battery has tabs attached you may want to contact Alinco and get a battery from them, soldering tabs on a battery can be difficult to battery destructive. Check carefully, it may be a simple battery holder and not attached clips. I have a DR570 that I haven't yet replaced the backup battery, I'll look if I have time tonight.

Note that you will lose all memory in the radio when you replace the battery and it's a good idea to do a full reset after replacing said battery, but from your posts it looks like the radio is not so great in the memory department anyway, an even better reason to do a full reset after a new battery.

Soldering the new battery in can be a challenge if you haven't done much soldering or component removal/replacement, you may want to either find a friend who solders well or take the radio to a repair shop and have them do it.

Good luck!

I have that book too. Great read, very inspiring! I'd love to build it, or something similar - but have insufficient time right now and too many other projects lined up. I can't offer any specific advice but I would say this would be quite an ambitious project and you'd need to be quite committed in order to complete it successfully.

Another great book is "Crystal Sets to Sideband - a Guide to Building an Amateur Radio Station" by Frank Harris K0IYE. This free eBook is available for download on my website at http://www.hanssummers.com/radio/k0iye/index.htm . Frank covers all the theory and simple circuits, building up to more complex rigs. A great resource for the homebrewer.

Tunes-

I'm not familiar with the 81438. The 87 may be similar to a 77 I used at work.

The 77 function switch has a vulnerability in that the knob and shaft that activate it are attached to the front, and the switch and PCB are attached to the back when opened to change the battery. The rotary part of the switch is floating and moved out of position when the battery was changed. Damage to contacts occurred when the meter was re-assembled.

You may prefer to call this "operator error", but I've never had any such problem with my 8020A which has a separate battery compartment and push-button switches. (Of course it is not auto-ranging!)

Given a choice, I prefer push buttons to a rotary switch, especially if settings are to be frequently changed.

PLONK'ed for weeks by me, as well. He's been asking the most basic,
lame electronic/radio/antenna questions in a variety of ng's.

Kinda reminds me of a clueless fella I once had the 'pleasure' of
working with at an old $DAYJOB. He would ask me the most basic
(computer/programming) questions - that his resume claimed he had
down pat - and I got tired of it.
I told'im: "I don't mind answering questions. But, you had better not
ask me the same damn question more than once." (And, he had been...)
That seemed to have mostly solved the problem.
Later I learned that he started using a list of the "experts" at the
$DAYJOB, and was methodically going round-robin to ask his questions.

He finally (re)embellished his resume and moved on down the road to
a new, unfortunate employer.

785. Is this voltage doubler different?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-01-31 20:53:51 UTC
From: Mike Silva <snarflemike@yahoo.com>
Message-ID: <1107204831.573023.87930@c13g2000cwb.googlegroups.com>
Source record: 20618

Regarding the circuit here:
http://www.kwarc.org/bulletin/99-04/tech_corner.htm

Does this voltage doubler work any "better" (better regulation, better transformer utilization, etc) than the classic 2-diode, 2-capacitor doubler (as seen in e.g. the HP-23 supplies)? I know it uses more parts; what I'm wondering is whether the extra parts actually provide any benefits, and if so, under what circumstances.

Does anybody have any actual experience with this circuit?
73,

==========
Just a construction hint. For a neat multi-turn rx loop you could consider ribbon cable as used in computing gear .
Some time ago ,at a fleamarket I bought a roll of 100 ft (30.5 metres) of 15 leads wide ribbon cable.

Example : To make a 4 turns loop as above you would need 2*4 equals 8 metres of 8 lead ribbon cable using end of lead 1 and 8 as ends of the loop , join ends of lead 2 and 3 , 4 and 5 , 6 and 7.
Although the ribbon leads multi-strand overall diameter is only 0.2 - 0.3 mm ,it should be OK for rx purposes.

If, as the author claims, it yeilds 120hz ripple, it will need
smaller filter caps than a regular doubler and provide less ripple
(lower hum). Diodes are cheap, caps are not (at least not HV high
capacitance ones!) though.

It will greatly depend on what your purpose it. I use the Fluke meters at
work. I may measuer a 20 milliamp circuit and afew minuits later measuer a
480 volt circuit that is fused for about 600 amps. The Fluke people came in
and did a demonstration on their meters. One thing that impressed me was
some films they showed. Just by subituting the wrong fuse in their meter
and haveing it set for ohms or amps instead of voltage and hooking it to the
3 phase circuit created one big arc and flash. The cheeper meters did the
same thing. Just imagin an arc welder running 480 volts and number 20 wire
shorting the thing out. Then you are holding a lead in each hand. The
insylation melts off the leads and you become part of the circuit.

The cheep meters are ok for some home usage but if going to higher voltage
and current you want to use a meter that will stand up to some abuse without
making you a part of the circuit.
You can buy 50 meters for what a good one costs but if using it on high
voltage/current you do not want to put your life on the $ 4.00 meter. The $
4 meters are fine for low voltage stuff and you can buy a few if they crap
out on you.

I don't see any difference from a regular voltage doubler with an
added filter cap at the output. C1 and C2 are still charged with 1/2
wave power.

It is more complicated than the normal full wave doubler,
http://hyperphysics.phy-astr.gsu.edu/hbase/electronic/voldoub.html#c1
but I can't see that it has any advantages.

Loops made of multi conductor cables in this way tend to have a very
large capacitance between turns and in the worst case the loop will
have a self resonance frequency below the desired frequency band. Even
if the self resonance is above the desired band, the amount of
external tuning capacitance is greatly reduced.

When a wide ribbon cable is available, it can be a good idea to use
only every other lead and let the intermediate leads floating to
reduce the capacitance between turns.

Build s test ckt with a filament xfmr and *small* caps and a "heavy" load,
and look at the oupt ripple with a scope. Or build it virtually.

OT: Which are the other good, (affordable!?) ckt sims?
Anyone have a transferable version of Electronics Workbench he'd like to
sell?

==========
Paul , Tnx for the above advice ,although for a loop made with flat multi
ribbon to be tuned to 60 kHz , the self-resonance freq will highly likely be
higher than 60 kHz . The ribbon I have is 15 leads wide ,hence for higher
freqs I could leave out every other lead .
Tnx again , this is good education .

Yes, both C1 and C2 are charged with 1/2 wave power (one pulse every full cycle). However, it appears to me that the difference is that they only discharge during one half-cycle of every full cycle. On the charging half-cycle they are not also discharging, but they only discharge on the opposite half-cycle. This is different from the 2x2 doubler, where both caps are charged on alternate half-cycles, but both caps discharge during the entire full cycle. If I've analysed this correctly, it seems that there should be some improvement in voltage regulation over the 2x2. But I wanted others to look at the circuit and offer their ideas on it as well.

With regard to circuit simulation: have a look for LTSpice on the Linear Technology website. Or if you don't mind text-based netlists and classical Spice, see http://www.rfglobalnet.com/IndustrySearch/SearchResults.aspx?keyword=Spice&TabIndex=4&image1.x=0&image1.y=0 for some other sources.

With regards the circuit, it's fairly easy to do some mental arithmetic to see if there is an advantage or not over the two-diode, two-caps, floating-transformer "full wave voltage doubler" circuit.

In the old circuit, there are, if you will, four distinct time periods in each cycle (though two of them are electrically equivalent, and the other two are symmetrical). One is where the upper cap is charging, and the load current may be considered to be through the two caps in series -- or may be considered to be through the lower cap and the transformer and upper diode. Following that is a period where the transformer voltage is too low to charge the upper cap and too high (not negative enough) to charge the lower cap. Then the load current flows through the two caps in series. Following that, the transformer charges the lower cap, and after that the transformer voltage is again too low to forward bias either diode. So the net voltage across the two caps increases twice each cycle, once when the upper cap is charging and once when the lower cap is charging. The output (load) ripple fundamental frequency is twice the line frequency. You can get a reasonable idea of the ripple voltage if you assume the charging takes place in a tiny fraction of the total cycle time; in fact, that will be an upper bound on the ripple voltage. For simple analysis, assume a 1Hz input so there are two charging pulses per second (one per cap), and assume two 1-farad caps and a 1-amp load. Then the voltage across each cap between the charging pulses sags at 1 volt per second, and the output sags at 2 volts per second, but resets twice per second, so the ripple is 1 volt peak to peak.

In the new circuit, you need to say something about the capacitor values. Presumably the two "input" caps are the same value, but may differ from the output cap. But what happens if you say that you are going to use the same total energy-storage ability as you had in the simpler circuit? Then the output cap might be, say, 0.25 farads, and the two input caps might be 0.5 farads each, since the output cap must be rated at twice the voltage of the caps in the original circuit. Now...can you figure out an allocation of the caps that gives you even the same performance as the original circuit, let alone a better one? And is it worth using more caps and more diodes? Especially for low voltage use, the original circuit has a distinct advantage of having only one diode drop during charging.

You can also analyze transformer utilization and I think you'll find
that the "improved" circuit doesn't really offer any advantage, if you
set it up to give the same output ripple.

Any other viewpoints, backed by some analysis or simulation?

Cheers,
Tom

Beyond 3 or 4 turns on a single-layer coil, the coil's resonant
self-capacitance is not very much related to capacitance between adjacent
turns.

This is because the individual between-turn capacitances are all in series
with each other and the resultant rapidly decreaes.

For a 10 turn coil the end-to-end capacitance due to adjacent turns is only
1/10th of the individual turn-to-turn capacitance.

Coil self-capacitance soon becomes a linear function only of coil diameter
and length of the coil former.

It's rather complicated but the resulting self capacitance is much smaller
and the resonant frequency is higher than what you think it might be just by
considering the individual turn-to-turn capacitances.

Reg, G4FGQ

Be sure to load each side of the AC source that represents the
transformer winding with a small capacitor to ground (something like
.01 uF) or the simulation will run slow. The source is constrained
only by the diode reverse bias capacitance during most of the swing,
so it takes a while for the simulation to scale up and down between
what is happening when the diodes are on and when they are off.

Series resistor on 75 ohm side is 43.3 ohms. Parallel resistor on 50
ohm side is 86.6 ohms.

814. I need to get some 1N34A diodes. Can you recommend a good supplier?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-02-02 00:18:55 UTC
From: Rick Gray <rgray@atlanticbb.net>
Message-ID: <110073imdb9vi77@corp.supernews.com>

I plan on building a crystal radio and need to get some 1N34A diodes. (I figure about 50 would last me a lifetime). Can anyone recommend a good supplier who has reasonable shipping charges? I see a bunch of people selling them but I don't want to spend more on shipping then I do on parts.

Also does anyone know where to get the old Quaker Oats containers? The ones I see in the stores have plastic tops.

Thank you for any help you can give me.

http://www.maxim-ic.com/appnotes.cfm/appnote_number/972

Their calcs yield a design with R1 (in series with the 75-ohm source)
being 43.3 ohms, and R2 (in shunt with the 50-ohm load) being 86.6
ohms.

That is the problem with buying small parts. The parts are about 10 for a
dollar and you pay for the small ammount shipping an handling. Try e-bay.

Here's some scans of old oatmeal boxes if you're interested. You can
wrap one a round salt box if you really want a cardboard form.

>
>73,
>Mike, KK6GM

It is true C1 and C2 are not discharging while charging. But when they
do discharge on the other half cycle they are being discharged more
than they would be in a regular doubler circuit.
They still each have to supply 1/2 of the output load at that time to
recharge the output capacitor. The output capacitor is getting
recharged through C1 and C2 only and not directly from the diodes and
transformer. So in effect you have 3 capacitors in series for the load
rather than 2 in a regular doubler.

Although at first glance it would seem that the output capacitor is
getting part of its charge through some of the diodes, it only does so
on the first cycle at startup . After that the output capacitor is
charged to a higher voltage than the transformer supplies directly.
That keeps the diodes directly from the transformer to the output
capacitor reverse biased so no current flows directly from the
transformer to the output capacitor.

So the output capacitor ends up only being charged by C1 and C2 on
alternate cycles. So it would seem that performance would be worse
than a standard doubler circuit. Unless much larger capacitors were
used.

Faint bells ring... 43 ohms is a standard value, and 86.6 is pretty
close to 100 paralleled by 680.

For testing 75-ohm TVI filters in a 50-ohm system, it's very handy to
make up a pair of those pads as inter-series adaptors.

Hello All,

I am trying to simulate a simpe AM receiver circuit with diode detector. I am assuming that the signal received from the antenna (simulated with a voltage source) has a weak amplitude (around 100 uV) and a high frequency (around 600 Khz). The issue is that the current after the diode does not get rectified. The output current is very weak (less than 250pA) and still contains the full sin signal (both halves of signals).

When I try the simulation with smaller frequencies (around 5kHz) and higher amplitude (around 0.2 v), the signal gets correctly half-rectified, but not anymore when I work with higher frequencies and smaller signals.

In real shematic for AM simple receiver, there is no ampification bewteen the antenna (and the tuning LC circuit) and the diode. So how the diode manage to half-rectifies correctly in real operating mode when the signal is weak and high frequencies, which is the case of real radio signals.

I use Ansoft Simplorer mainly. Any other simulators recommended ?
Thanks in advance and best regards,

John.

The answer to your question is that real, simple AM receivers - crystal sets - only work where the received signal is quite high. They tend to use fast, low capacitance diodes. The term "rectifier" tends to be used for bigger, slower diodes basically intended to handle around an ampere of current from a 50/60Hz source, that look like capacitors in RF circuits.

Practical AM receivers always amplify the signal before they detect it, and usually "mix" the amplified signal from the antenna with the output from a local oscillator at different, if similar, frequency chosen to be 455kHz away for the transmitted signal. The nominally 455kHz component coming out of the mixer is then filtered by an elaborate bandpass filter to reject all the other components, further amplified, and only then detected.

Search on "superheterodyne".

What makes you sure the simulation and the reality agree ?
There is capacive coupling over the PN structure of the
diode to start with. And then at one point a diode has
an exponential characterization instead of binary on/off.

hi,
I search for the part number in google like this and then I get the mouser page
fast,

google search for : in34a mouser.com

http://www.mouser.com/?No=90&handler=data.listcategory&N=500

http://www.mouser.com (Germanium 34 cents each in 100 or 41 cents by 10's)

no minimum order, great online website, fast searching.
select us mail for lowest ship cost.

Received my copy of "Volume 24, Winter 2004-2005 QRZ Callsign Databae" last
year sometime. I remember it came in the mail the day after they said it
would be available. The charge showed up later.

You're going to get some flak from the crystal radio crowd on that one.

Crystal radios generally step up the voltage from the antenna, and use a
sensitive, high-impedance earphone -- and still require relatively
strong signals to receive well. For packaged diodes consider a
point-contact germanium or a zero-bias schottkey (although the real
crystal fans will want you to stick with germanium or other material,
per the other poster). Clever tricks to play include audio
amplification after the diode and a very slight forward bias applied to
the diode.

Hi,

In days of yore a crystal set would have had a longish wire aerial (several millivolts output), a high-Q tuned circuit (further magnification) and a high-Z load on the detector all, of which lessened the need for a perfect characteristic.

And that's before you placed the headphones in a pudding bowl.

Cheers - Joe

I ran simulations for both circuits. With the basic assumption that the output voltage being developed is large compared to the diode drops, I can't find any advantage to the more complex circuit.

In both circuits the transformer supplies energy on each half cycle. The ripple at the top of the single capacitor in the complex circuit is the same as the ripple at the top of the 2 capacitor string in the simple circuit. The ripple at the output in both cases is 120 Hz for a 60 Hz supply with identical magnitude. The ripple at the junction of the two capacitors in the simple circuit happens to be 60 Hz. I varied the load and the regulation appears identical for both circuits and is mostly a function of the source resistance of the transformer (not terribly surprising). The series resistance added by the diodes would generally be an order of magnitude smaller for high voltage supplies and not a big factor in either case assuming these are high current diodes.

The simple circuit has the advantage of being able to easily supply both a double voltage 120 Hz ripple output and a standard voltage 60 Hz ripple output.

In a power supply I built for a Heathkit SB-101 a long time ago I took advantage of the two outputs from a simple doubler. The 850 V output went to the finals. Then from the 425 V output I added a divider and additional filter capacitor to provide the 300 V supply. By providing a load resistance across the upper cap similar to the load resistance of the divider on the lower cap the equally shared voltge was maintained at the two filter capacitors. The divider on the lower cap allowed me to tap off at a 300 V point to which I added a little additional filtering (remember that point has 60 Hz ripple). By doing this I didn't need a separate winding or transformer for the 300 V supply. I used an old 300 VRMS TV transformer for both my 850 V and 300 V supplies. That supply is still in use with original components 35 years later.

For the simulation of the complex circuit I used a 50 uF output filter and for the simple circuit I used two series 100 uF capacitors to provide the equivalent filtering (i.e., 50 uF).

So, all I can tell is that the complex circuit takes one extra 50 uF capacitor, and 4 extra diodes to do the same job as the simple circuit with no difference in efficiency that I can find.

==========

A simpler logical analysis -

The more complex circuit will have lower efficiency because it does exactly
the same job with 5 additional components to lose power in.

Back to the drawing board !

Should not we expect that the current, even at very small level, to be
half rectified by a diode, since the reverse resistance of the diode is
supposed te be far greater than the forward resistance?

Why can't we found this result in smulation. Is it a flaw in the
simulator (Simplorer) or is the theoric behavior of a diode that
changes in case of very small input ?

Regards,

John.

One of the Profs in college built a "crystal" radio that was powerful
enough to drive a loudspeaker. It played day and night in the lab.
He had it set up so he could change the detector, but left the LED in
there because it worked as an "on" indicator too. ;-)

I think a way of looking at the difference is that one is two half
wave doublers in series and one is two half wave doublers in
parallel. You would have a hard time using the parallel version if
you wanted an 800 volt output and intended to use electrolytic
capacitors, because each of the 3 would have 800 volts across them but
it may have some utility for low voltage outputs. There may be a
better way to connect the diodes, but I haven't got that far, yet.

The diode behavior is a continuous curve, so for a small AC voltage you
won't see much change in the diode's resistance even at zero bias.
Unless you're modeling a really leaky diode, however, you are probably
seeing a situation where the diode's resistance is effectively shunted
by it's capacitance and you are seeing capacitive coupling rather than
conduction.

Yes, I am like that with books. I will probably
never be able to switch to eBooks or whatever.

I know it is an emotional issue with some, but
you can print them, right? I should be getting
HB #4 any time now and look forward to it.

It really does seem like a bargain to me at $15/yr.

The point about continuous curve is well made.

The diode doesn't have to hard rectify. As long as it has a non-linear V-I
graph it will produce some audio. The more sharply curved the
characteristic, the more audio is produced.

In the valve days, the anode bend detector worked that way, using a valve
biased to operate on the curved part of the characteristic.

I am very sure that QRZ.com is very much aware that they must not charge
your credit card until shipment has taken place. The fact that they did
tells me that you need to report to them that nothing has been received and
ask them to trace the shipment. They are just too reputable, a break down
in the shipping path has occured.

Diodes have a tresholdvoltage of 0.3-0.7 V.
The amplitude must be greater. That is why this
type of receiver requires a large antenna or a
transmitter nearby.

There is nothing wrong with the simulator... the problem is with your idea of a diode. The general definition of a diode is a component that conducts normally in one direction, but does not conduct in the other. That definition only applies to a "perfect" diode. The reality of semiconductor diodes is that a 'barrier potential" exists across the junction. In germanium diodes, this is around 0.3 volts; in silicon diodes, it's around 0.6 volts.
In order for the diode to conduct, this barrier potential must be exceeded by an externally applied voltage. Until that potential is reached, the diode is said to be reverse biased, and only a very small leakage current flows. When the barrier potential is reached, the junction becomes forward biased and conducts heavily.

The small signal voltage that you are trying to simulate may not be enough to reach the barrier potential of the diode junction, thus, no conduction (rectification) in either direction. The simulator is aware of the barrier potential of the diode. If the peak value of your signal voltage is less than the barrier potential, no rectification occurs. If you increase the amplitude of the signal applied to the defined barrier potential of the particular diode in your model, you will see rectification begin. The higher the signal amplitude, the more rectified signal appears on the output.

You can make a diode rectify a signal amplitude lower than the barrier potential by applying a forward voltage that is just under the barrier potential, so that the signal doesn't have to overcome the full barrier potential. Fer instance, if you apply a 0.5 volt DC voltage to a silicon diode, it will start to rectify signal levels as low as 0.1 volts.

Hey, have a '78 model Alert Monitor, M03CNB1102B
VHF unit, silver front with black case, reset/alert/mon functions.

Questions:
Original battery type, location, voltage?
Frequency range? Will it do 146.000MHz?
Is it possible to turn down the volume on the alert tone?

Need schematic, tuning and recrystal instruction.

Any help appreciated,
thanks,
rb

Dave, your considerable effort to explain the nuances of diodes to John
is commendable, but your explanation is rather misleading. It's not true
that for a diode to conduct, the "barrier potential must be exceeded,"
and "the junction becomes forward biased and conducts heavily." Instead

the diode current has an exponential relationship to the voltage across it, and gradually turns on over many hundreds of millivolts, not abruptly at say 600mV. Here, examine some diode measurements I made a long time ago, http://www.picovolt.com/win/elec/comp/diode/diode-curves.html

For example, these plots show that an ordinary 1n4148 class of silicon signal diode, which conducts about 0.5mA at 600mV, is still working at 250mV, conducting 1uA in my measurements. In fact, this diode was still conducted at 100mV. See http://www.fairchildsemi.com/ds/1N/1N4148.pdf where Fairchild's datasheet also shows this exponential relationship, albeit drawn with a draftsman's straight line.

So, as others have pointed out, diodes can rectify very small signals. They may not be very efficient, but they will work. These plots also show how Schottky diodes (e.g., 1n6263 and 1n5819) are better than ordinary silicon diodes at low voltages, even below 100mV. The 1n6263 may be hard to get, but other parts, like the sd101 or bat17 may not. http://www.vishay.com/docs/85629/85629.pdf

There are other diodes that work well at very low voltages, notably some made by Agilent (see an1090), but we won't go into them here.

The difficulty is "what to do with that 1uA current". To put it to practical use, a signal processor is needed that has a useful output. For example, a MOSFET amplifier with a 10 megohm input resistance and negligible input capacitance (for low frequency sigs) could be used.

In this case it would be better to rethink the project.
In addition to the diode, some system design is indicated.

Hi Rick,

Mouser has them as NTE replacements at .41 ea. The shipping should not be too bad on these. Would be worth it if you could add some other parts to your order.

http://www.mouser.com/index.cfm?handler=displayproduct&lstdisppproductid=411183&e_categoryid=131&e_pcodeid=52602

Also, look for 1N270. These are also GE devices and I think they are more available.

A little off topic, but have you checked out the Xtal Set Society? If you're going to get into crystal sets (a great idea!) then you'll probably want to check out they're newsletter and site. Their part's aren't the cheapest, and I would suggest the other suppliers mentioned in the thread, but the source of information is great.

As for the Quaker Oat containers, do you have to have Quaker? I've found many generic brands in my area (great for my use since they are cheaper, and I don't eat that much oatmeal, but do use them for xtal set ideas from time to time) that still use the older style container. Try your local "dollar" stores and such.

Good luck with the project!
Jeramy

Yes its what you'd expect. As I explained on the thread "Junction
capacitance of diodes and zeners" the Capacitance of a forward biased
diode increases with the applied bias or if you do the math you'll
see it increases exponentially with it. They are actually 2
capacitances in consideration but thats another question. Its really
hard modelling a non linear component with linear components but the
following can be said to be true for small variations of voltage. You
get your desired precision by adding up together pieces of this model.
If you look at a piece wise linear approximation model of the diode
you'll see it has a conductance or a linear dependent current source in
parallel with 2 condensers and the current through the conductance is
Is*exp(Vapp/Vt). Vapp is the voltage across the condensers. At high
Vapp and low frequencies from above C is high and has a lower
impedance so Idiode is high. At higher frquencies Vapp on the
condensers is pretty low so Idiode is also low. If Vapp is lower you
get an even lower value.

Well if you want to cheat you can have more turns on the primary then the secondary of the input transformer and you get a higher voltage (grin). I'd have to see the exact circuit you are talking about to be of more help.
Good luck.

Hi,

I have re-done the simulation with the diode 1N41481, and it rectified.
Thanks.

For the 600mv, it did give indeed around 0.5mA. I even tried at 100mv
and at 100uv, and it still conducts (respectively 60uA and 25nA).

Regards,

John.

No it's true. Look at the curves and notice that the current scale on
the x axis is a log scale. When the RF input is very small, the DC out
is proportional to the log of the RF level i.e. the RF in dB. This is
how the normal power meter works. It also provides a true RMS value
for modulated RF signal. Once the signal gets too big and the diode
begins to work as a converntoin rectifier, this relationship no longer
holds true. Notice the curves break upeards. When the RF volatge to
log I curves are straight line, this is rhe square law region where the
diode current gives you true RMS readings of the RF voltage.
Think of it as a voltage in dB to current converter.

Mark

The Desrt Ratt HR regenerative receiver has a good reputation, and I'd
love to build one, but I am a quite mediocre homebrewer... If I can
get some potential problems out of the way I can better concentrate on
the many others that will surely crop up!

These are my doubts w.r.t. the DR2 as described in the .PDFs on Paul
Harden's page:
http://www.aoc.nrao.edu/~pharden/hobby/DR2.pdf
http://www.aoc.nrao.edu/~pharden/hobby/DR2descr.pdf .
Can anyone comment on any of these points?

1) Tuning Coil

The PDF mentions inductance, number of turns and wire gage,
but leave us in suspense apropos the coil former:
"T1 is wound directly on the PCB". Uh?
I guess anything 5-6uH will do, but I can't keep from wondering...

2) Tuning Varicap

"R5 sets the current across D2-D3" The reverse resistance on such
rectifiers is huge, much greater than R5 (10kohm). I noticed that Paul
Harden N5AN once offered V/C measurements on diodes for use as varicaps
(http://www.kkn.net/archives/html/QRP-L/1998-01/msg00360.html)
There, one sees a 1N4148, forward biased. From the specs one gleans
that this diode has a sizeable current when forward biased at voltages
within a reasonable tunng range - but we're talking about something
quite different here. What gives?

3) Q2 (oscillator) biasing

The resistor between C6 and C7 is not rated. A base bias on an regen's
oscillator can be rather, well, critical....

4) IC Amplifier

R12 is indicated as "10W".
What would a reasonable resistance rating be?

5) Voltage Regulator

The text says that the drop across the forward biased LED1
is 1.3-1.8V, while across the Si rectifier D1 is 0.7V.
In series they'd sum up to 2 - 2.5V, but on the circuit
one reads a total drop of 3.0V, i.e. up to 1 V higher.
Charles Kitchin's design fed the oscillator just 2.1V...

Would 2.5V be enough? Or, do LEDs come with a wide variety
of voltage drops?

TIA to everyone!

I hope this will encourage others to experiment with this circuit.

Indeed, as Win says, you can get some signal out of a diode detector even for very low input levels. With fairly simple home-brew techniques but a lot of attention to the details of leakage currents and op amp offset voltages, I'm able to detect RF signals down to a very few tens of microvolts. That's using either a zero-bias Schottky detector diode such as the Agilent HSMS-2860, or an old germanium point contact diode. At very low signal levels, the optimum load resistance is quite high. (See Agilent detector diode ap notes for details.) Things are actually easier if you're only interested in the modulation component of an AM signal, and not in trying to detect the carrier level, since the offsets aren't particularly important for AC signals. A JFET audio amplifier, or even a carefully-designed bipolar amplifier, can give you a very low noise figure for the high source resistance that the diode detector running at low input levels gives you.

There are tricks you can play to make a receiver that works from the power received by the antenna. If you live near a transmitter that's putting out significant power in your direction, you may be able to set up a rectifier for that received power and use it to run a micro-power amplifier following the detector for the station you wish to receive. If you want to hunt for weak stations, you'll need a carefully designed and built RF input tank/filter circuit. At night, especially, it's possible to listen to stations quite a ways away using no active components in the RF path before the detector.

Cheers,
Tom

You'll find that in reality something your simulator won't take into
account that its preferable to transmit at higher frequencies because
reception is better as the 1/f flicker noise is reduced to lower
values. Thats just 1 of the several reasons why frequency multipliers
are used in transmitters and downconverters in receivers.

The theory confirms your results.

I diode ~K*exp(Vsignal/Vt) =K+ a*Vsignal + b*Vsignal^2+ .... by the
binomial theorem

So at low signal amplitudes the diode current follows a linear
relationship as predicted by the diode equation and confirmed by the
graphs there. At higher values the higher terms start dominating and
the exponential term takes over.

871. Re: I need to get some 1N34A diodes. Can you recommend a good supplier?

An average shipping charge on a small quantity of parts such
as 100 or less small-signal diodes is roughly $9US.

At www.circuitspecialists.com you can get 1N34s for 14 cents
at 100+ or 16 cents at 10 to 99 or 17 cents at quantities 1 to 9.
If you purchased 100 diodes the total price would be equal to
23 cents per diode. Buying 10 would be equal to $1.06 per
diode. But that's if ALL you bought was the diodes. Circuit
Specialists (prompt good supplier) has lots of hobbyist electronics
and some nifty deals on instruments (check out the Protek 100
MHz dual-trace scope for $500...new, not "seconds"). For
orders over $50 you can get a nice promotional item (last
year's item was a nice 3 1/2 digit DVM. good all-around meter).

Going to www.oselectronics.com (Ocean State Electronics in
Rhode Island) you can find some nice prices there on many
things plus lots and lots of single and multi-gang variable
capacitors (expensive because those are rare items nowadays).

Digikey in Minnesota has all sorts of new components of a wide
variety and will waive shipping charges on orders over $25 (?).
www.digikey.com

Until chain drug stores carry germanium diodes on easy-to-grab
sales racks, expect to pay at least $9 to get any small, low-weight
mail order delivery via FedEx or UPS. Or go to a Radio Shack
store and pay much more (if they have it) and spend gas driving
to it.

>Also does anyone know where to get the old Quaker Oats containers? The ones
>I see in the stores have plastic tops.

"Plastic tops" won't hurt any hand-wound coil done in the old, old
traditional manner of crystal sets. If it has a metal band somewhere
in that circular container, you've got big trouble from the "coupled
shorted turn" effect lowering the inductance. [plastics used in most
packaging are non-conductive]

A better bet is to visit an office supply store chain such as Office Depot or Office Max and check out the cardboard mailing tubes both carry. All kinds of diameters and lengths to choose from. The cardboard is thicker and sturdier and will have some slight effect on copying a traditional oat-box coil former, but not over a few percent off.

For a VERY sturdy coil former, DIY stores usually carry ABS waste line pipe stock, diameters roughly to 4 inches with thick walls. ABS (acrylonitrile butadiene styrene) plastic is non-conductive, non-magnetic. Check out the plumbing section at those stores.

> Is it possible to turn down the volume on the alert tone?

In sequence:

Unknown. Best to adapt it to an external 12VDC supply.

Possibly. The VHF alert monitors were spec'd to bottom out at
150MHz. It may be possible to take one lower by increasing the value of
the padding capacitors across the receiver's oscillator and multiplier
coils. It is possible that it may go lower on its own. Never know until
you try.

> Need schematic, tuning and recrystal instruction.

That could be difficult. The manual for this receiver was Motorola
part #68-81048A55. This P/N comes up as no longer in the database, which
means that it is no longer available from Motorola (considering the age
of the unit, and Motorola's feverish desire to gain profit at any cost,
I'm not surprised).

You should check in with the gang at Batlabs
(http://batboard.batlabs.com). They may be of further assistance.

Happy hunting.

I know where you're coming in from, but whichever way I look at Win's graphs
I'm seeing a straight line for that 1N4148 at 0-30mv levels. Yes, the scales
are log-log but the constant of proportionality is dead straight linear. I.e
1mv RF in gives 1e-10 amps and 10mV in gives 1e-9 amps and pro-rata for all
points in between (you did see the double decade increments?). This agrees
with the 10Mohm value that's marked on the graph.
It shouldn't matter if the RF signal is swept over a 1 to 30mV range or just
a 5 to 5.01mV range, the DC out will be directly proportional to the 'DC' in
and no distortion of the waveform can occur, hence no dc offsets or
harmonics.
The graph next door though , the 1n5819, looks like it could offer up a tad
of rf dB-I rectification. Though to my eyes it still looks way more like a
resistor than anything with a square or log law response.

There'll be better devices out there that offer (say) quadratic like classical responses at these low levels but it's moving out of the 'common or garden' playground.

10's of uV. Egad!. Wish I had your patience!. Built a feedback linearised RF
probe head last year, using a couple of dual BAT85 SM packages in its tip.
They were used as voltage doublers working into 10Mohms. I tried really,
really hard, (well, about an hour) to see a mV of RF i/p but random DC
shifts, thermocouple effects and second order temperature drifting called a
halt to the project. Wish I'd thought about these things before starting :-(

Right, but that part of my measurements cries out for further bench
exploration. It represents only one part, and is unconfirmed. Also,
what happens if the voltage is reversed? Are we to believe the diode
is a 10M resistor, shunted by a diode? I'm not comfortable with that.

Here is a link to a few pictures of an older version of the Desert Ratt.

http://www.njqrp.org/qhbextra/2/2a.html

You have to scroll down a little bit, but this shows that the coil is wound on a toroid. As long as it has good characteristics in the 3-30 MHz range, any one can be used. The permeability may vary from one toroid to another but you should be able experiment a little to get things right. Maybe someone else could suggest a proper toroid number. The one there looks like a T50-?? or T38-??. It's hard to tell.

> quite different here. What gives?

Yes, forward biased the 1N4148 will have a high current. If you read further through that thread, someone else described a problem with using it in that mode. The high current caused excessive heating and drift. Not really recommended for use.

> 3) Q2 (oscillator) biasing
> -------------------------
> The resistor between C6 and C7 is not rated. A base bias on an regen's
> oscillator can be rather, well, critical....

C6, C7, and R? are there to filter and stabilize the Base-Emitter voltage and bypass the Base-Emitter junction from RF. A value of 100K should be sufficient. The value isn't really that critical.

Here is a link to a really old version of the Desert Ratt.

http://duke.usask.ca/~buydens/ham/ratt/index.htm

The coil is different but the biasing structure of Q2 is pretty much the same. Also note the slightly different part arrangement on the lm386. Get a spec sheet on the lm386 to see what each part is suppose to do.

> 4) IC Amplifier
> ------------
> R12 is indicated as "10W".
> What would a reasonable resistance rating be?

This just looks like a misprint. I believe that should be 10 Ohms. Just go to google and type in lm386 for all the information you can stand on that chip. I didn't see any configuration that used it in quite that way, but that doesn't mean it can't be used that wy.

> Would 2.5V be enough? Or, do LEDs come with a wide variety
> of voltage drops?

The voltage drop across the diode D1 will be as specified for just about any 1N914 you use, however, the voltage across a LED depends on exactly which one you choose. Here is another link to a page that describes the kind of voltage drops you can expect from LEDs.

http://www.theledlight.com/LED101.html

It seems that this value can be any where between 1.7 and 4.6 volts depending on the type you choose. I seem to recall that even when you get a LED from Radio Shack the specs are printed on the back. Personally, I would shoot for the 3.0 volts, listed in the schematic.

Yes. Ive been mulling that over. If there is no static bias current flowing
through the diode and it magically switches to 'open circuit' when the
incoming voltage reverses sign, then it would still make a perfect 'average
respsonding' rectifier even at these mV or even uV levels. Just how does the
reverse current start to act in the reverse direction?. On the face of it, a
IN4148 seems easy enough to check out.

Input transformers are all very well, but some good voltage step-up
can be obtained by carefully chosen values of hi-Q capacitor and
inductor in series between the aerial and the diode. Of course this
makes the impedance even higher, just as the transformer would, but
how strong's your signal? It might be the cheapest alternative.

I'm confused. Is there some reason to expect the semiconductor material to be a perfect insulator with no resistivity at all? Nothing's perfect, and those diodes probably aren't made in the most exacting processes.

I would be blown away if you *couldn't* measure some ohmic current flow in a diode at any particular voltage level.

882. Tuned circuit Q question

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-02-04 22:48:56 UTC
From: hexter@blazenet.net
Message-ID: <1107uuo52qbdb91@corp.supernews.com>
Source record: 20515

The source is 50 ohms, I am feeding through a 1000 ohm resistor to
my tuned circuit at 30mhz, and the load is over 5000 ohms (FET input).

I want to use a parallel resonant circuit to ground to form a pass
filter. If I want a Q of around 5, would I need 5000 ohm XL/XC ??

This would seem nearly correct. Have I calculated correctly?

883. Battery problems on IC2-SRA

Hi,
Not sure this is the right spot to post this so please forgive me if its not. I have an Icom IC2-SRA 2mtr/scanner. The batter pack died on it and before I could replace it, the memory battery also went south. I used to be able to power it up with the plug in PS and listen to it but now it doesn't power up at all. PS is ok. I tried the reset for the processor but still nothing. Short of sending it in to Icom for repair, I thought I would ask for any advice here as to how to bring this rig back to life. I know I need to change the batteries, but will that get the rig working again, since its not operating off the PS now? Does anyone have any experience with these handie talkies? TIA
73,
Brian

>
> This would seem nearly correct. Have I calculated correctly?

Not quite. Loaded Q is dependent on ALL losses in parallel with a parallel-resonant circuit. If you want a Q of around 5 then the R:Xc or R:Xl ratio is 5.

A problem seems to be the loading of the 50 Ohm source plus a series (?) resistance of 1000 Ohms. That alone puts 1050 Ohms in parallel with the resonant circuit. If the total parallel R is 1050 Ohms, the total from FET input and coil's own Q is 5000 Ohms, then the total parallel R will be 868 Ohms. The inductive reactance would have to be 1/5th of that or equivalent to 0.921 uHy. The Xl of 0.921 uHy is 173.6 Ohms at 30 MHz.

The problem is compounded by using a series resistor to feed the parallel resistance. If the resonant circuit has a total parallel resistance of 5000 Ohms, the magnitude of the impedance is that value, 5000 Ohms. But, with a series resistance from the 50 Ohm source there's a power loss from the equivalent voltage divider action equal to 5:6 or about 1.6 db at 30 MHz resonance.

It would be better to use another way to couple the 50 Ohm source, such as a tapped inductor. Tapping down at 1/10th of the turns has an approximate 1:100 impedance change which would transform the source to be about 5000 Ohms across the parallel L-C. That would change the needed inductance to get the loaded Q but there would be no extra losses involved. The new inductance value at resonance would be about 2.65 uHy for an Xl of 500 Ohms (1/5th of 5000 in parallel with 5000 Ohms).

Note: At resonance (and only at that frequency), the impedance across the L-C is entirely resistive. At any other frequency it is a complex number (both R and jX).

The PS may be sufficient to trickle charge the batteries, not enough
to actually power the unit. This is very typical for HTs. The battery
may be a necessary part of the circuit, even when running from wall
power.

It may be less expensive to buy the AA battery pack and drop in
regular alkalines or rechargables.

A good dealer who does service on Icoms should be able to explain your
options. Replacing the internal memory battery is no biggie for a
service center. It may be preventing a proper reset.

Happy trails,

Test on a 1N4148.
ForwardV DiodeR
+50mV 8megs.
+30mV 9megs.
+20mV 10megs.
+10mv 12megs.
+5mV 21megs.
ReverseV
-5mV 21megs.
-10mV 30megs.
-30mV 270megs.

All the figures are suspect as the noise filter had a long settling time
and I was too lazy to wait but they do show a very sharp reverse cutoff, at
about 10-15mV.

And a bonus, a rectification test feeding the diode from a 60Hz source and
10k series R ...

ACi/p DCo/p
430mV 59mV
300mV 12mV
200mV 2.4mV
100mV 140uV
60mV 66uV
30mV 18uV
20mV 9uV
10mV 1uV
regards
john

887. Radio Free Colorado - A Successful New Internet Radio Station

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-02-05 04:41:35 UTC
From: Gary Burke <nospam@noreply.net>
Message-ID: <BE299C8F.7AF6%nospam@noreply.net>
Source record: 20520

Radio Free Colorado - A Successful New Internet Radio Station

NOTE: NEW CONNECTION URL'S GIVEN AT BOTTOM OF MESSAGE!

Radio Free Colorado
What Radio Once Was

Radio Free Colorado, a non-commercial Internet Radio Station, plays a lot of music you probably haven't heard in such a long time and have since forgotten how much you love. It's such a thrill when a forgotten song comes on and you say "Hey, I love this song" and all your fond memories of it come rushing back to you.

Our "Genre" (what kind of music we play) is VERY diverse. We play Modern/Classic Rock, Progressive Rock, Alternative (Modern and Retro), Pop, Billboard Classics, and Top Radio Hits from the 60's, 70's, 80's and 90's. We also play some Ambient/Instrumentals. No Rap or Hip-Hop, Classical, Jazz or Swing.

Radio Free Colorado streams music LIVE over the Internet using a high-fidelity 128 kbps MP3 stream. We use professional sound processing equipment to achieve a sound quality which we believe is superior to virtually all other 128 kbps streams.

Any computer with a DSL, Cable Modem (or faster) Internet connection that has a download speed capacity of at least 128 kbps can tune in.

Virtually all MP3 music players are capable of receiving live MP3 music streams over the Internet. Any music player compatible with streaming MP3 audio can receive Radio Free Colorado's broadcast.

Our MP3 broadcast stream is compatible with virtually all music software programs and works with PC's running Windows, Apple computers running OS X and other machines running Linux or Unix.

Radio Free Colorado is NOT beholden to anyone. There is no pre-approved "playlist", no one tells us what we can't play. Listeners can, however make song requests and if we have it we will play it.

Radio Free Colorado - Sample of Songs We Play

Go-Go's - Head Over Heels
Dire Straits - Walk of Life
Aimee Mann - Save Me (Acoustic - Recorded Live) - KBCO Studio C - Volume 14
Nena Hagen (Gabriela "Nena" Kerner) - 99 Luftballons (German) - 99 Luftballons
4 Non Blondes - What's Up
Cake - Short Skirt/Long Jacket - Comfort Eagle

Cracker - Euro Trash Girl - Garage d'Or
The Carpenters - Live At The Palladium 1976
Heart - Barracuda - The Essential Heart
Tom Petty & The Heartbreakers - You Don't Know How It Feels - Wildflowers
A Flock Of Seagulls - I Ran (So Far Away) - The Best Of A Flock Of Seagulls
Alphaville - Forever Young (Live) - Forever Young
Heaven 17 - Let Me Go (Original Unedited Version) - CD Single
The Waitresses - Quit - Wasn't Tomorrow Wonderful?
The Jam - Going Underground - The Sound of the Jam
Yaz - Situation (US 12" Mix) - Upstairs At Eric's
Slow Children - Vanessa Vacillating - Best Of Slow Children
Tori Amos - Silent All These Years - Little Earthquakes
Pink Floyd - One Of My Turns - The Wall (Disc 2)
Haysi Fantayzee - Shiny Shiny - Battle Hymns For Children Singing

XTC - Dear God - Skylarking
Big Country - In A Big Country - The Crossing
Peter Murphy - Cuts You Up - Deep

These songs are just a partial list of some of the "rarer" songs that not only don't get played on the radio anymore but are hard to find as well. Virtually all of the songs on this sample list have long since been sent to the record company boneyard, which is why we play them. We have over 1,400 songs of all varieties and the list grows every day.

Artist and Song suggestions and requests are gladly accepted! We would like to grow RFC enough to satisfy a variety of tastes yet remain completely non commercial.

iTunes, RealPlayer, Winamp or Audion 3 (Mac only) are recommended for best listening quality.

Here is a list of recommended MP3 software programs you can use to listen to RFC's broadcast. They are all available for free.

iTunes Version 4.7 for Windows or Mac:
http://www.apple.com/itunes/download/

RealPlayer Version 10 for Windows:
http://www.real.com/affiliates/superpass.html?pcode=cj&src=cj

RealPlayer Version 10 for Mac:
http://www.real.com/?src=blackjack

RealPlayer Version 10 for Linux:
http://www.real.com/linux/

Winamp 5.08 from Nullsoft for Windows:
http://www.winamp.com/player/

Note: If you are using an earier version of Winamp, Nullsoft urges you to update
your software due to several "security flaws" that are fixed in version 5.08.

Audion 3 for Mac:
http://www.panic.com/audion/
Audion is now free of charge. Use the following link to get a free serial number for registering Audion:
http://www.panic.com/audion/buy.html

XMMS, MPG123, etc. MP3 Players for Linux/Unix or X Windows users:
http://www.uk6x.com/applicationservices/mp3radio.html

The "URL" address (the location on the Internet of Radio Free Colorado's Broadcast) is:
http://kara.fast-serv.com:8630/

For iTunes use the URL address:
http://kara.fast-serv.com:8630/listen.pls

For RealPlayer use the URL address:
http://kara.fast-serv.com:8630/listen.pls

For Winamp use the URL address:
http://kara.fast-serv.com:8630

For the Audion 3 media player, use the URL address:
http://kara.fast-serv.com:8630

You can find where to type RFC's "URL" address into iTunes under the menu item "Advanced" - "Open Stream".
For RealPlayer, look under "File" - "Open Location".
For Winamp, look under "File" - "Play URL".

We genuinely welcome Artist and Song suggestions, listener comments, etc.
You may contact Radio Free Colorado by visiting our website at:

http://www.boomspeed.com/garyburke/radiofreecolorado/RadioFreeColorado.html

Radio Free Colorado is protected under Copyright Law.

It is legal for you to listen as long as you don't record. :-)

Best wishes,

Gary Burke
Owner/Operator

I see my error, the XL/XC is one fifth, not five times the R.
I see this now in tank circuits where Q=10 R=2000 XL/XC=200.

O.K., now I can calculate my parts. This is for a bandpass
preselector, and loss is no problem, there is plenty of drive
available. I just need some relative measure of if any power
in the total signal level happens to be at 30mhz plus or minus
about 250kc at perhaps a 3db slope.

> in a diode at any particular voltage level.

Agreed. It's the rather low 10M value that raises my eyebrows.
Hence my suggestion that the measurements be revisited. Picked up
by John Jardine, who obtained similar values, copied below:

Test on a 1N4148.
ForwardV DiodeR
+50mV 8megs.
+30mV 9megs.
+20mV 10megs.
+10mv 12megs.
+5mV 21megs.
ReverseV
-5mV 21megs.
-10mV 30megs.
-30mV 270megs.

John also suggests the measurements may need further refinement.

Oops! I can think of several circuits I've designed over the years
using diodes for discharge protection that might not work exactly as
I intended, given this observation. And I recall several circuits
where I intentionally back biased the diode a few hundred millivolts
to insure an open circuit.

Thank you Martin! Great pointers! {grrr... I hate it when Google's interface gives u no feedback & u end up reposting n times.... apologies for not using a serious news client}

I also got very interesting replies directly from Paul Harden.

Paul ran into some personal matters that required much of his attention for a while, but he's well aware that the latest PDF on his site has a few issues.

On Wed, 2 Feb 2005, Filippo Cattaneo wrote:

> 1) Tuning Coil
> --------------
> You mention inductance, number of turns and wire gage,
> but leave us in tantalizing suspense w.r.t. the former:
> "T1 is wound directly on the PCB"

I did the webpage about a year ago when I began designing a kit version for the DR2. Since then, my xyl broke her foot, an extremely heavy work load, and recently, a QRP club trying to kit the DR2 without my permission. So I temporarily removed the coil winding info. I am hoping to fire things back up to get the DR2 kitted this summer.

The problem with a kit, to make things consistent, is winding the coil. For one-of-a-kind homebrew, you can use anything, such as the 35mm film can suggested, etc.

> - as if there was some secret advantage
> in winding "on the PCB".

Nothing secret. For the kit, the coil will be wound directly on the board, that is, there will be two "slots" tooled into the board for winding the coil. It works surprisingly well and a fairly decent Q. It is an approach much easier than other first-time kit methods of winding a coil.

> I guess anything 5-6uH will do,
> but I can't keep from wondering:

That is a good range if you are using an air variable in the 200-300pF range.

With using back-biased diodes as varicaps, such as the 1N4004, you only get about 60pF of tuning range, and the new prototype I'm working on about 80pF. For that reason, you want to have the coil inductance in the 2-3uH region for wider tuning.

> - p-Chloro-alpha,alpha,alpha-trifluorotoluene?
Yes, that's my secret, but keep it
under the rug for right now :-)

> 2) Tuning Varicap
> ----------------
> "R5 sets the current across D2-D3"
> The reverse resistance on such rectifiers is huge,

> I noticed your V/C measurements on diodes,
> (http://www.kkn.net/archives/html/QRP-L/1998-01/msg00360.html)
> and also that a 1N4148 has a sizeable current when forward biased
> at voltages within a reasonable tunng range -
> but we're taling about something quite different here.
> What gives?

I've never found 1N914/1N4148 to be very consistent, and in fact, some batches I've tested have the maximum capacitance when forward biased. I prefer the 1N4004/4005 series, as the V/C response is very consistent. Much of the idea of the DR2 is to build it with very common components. Obviously, a 100-200pF range varicap would be ideal, but they are hard to find and expensive. R5 can always be tinkered with to get the maximum tuning range for the diode that is actually selected.

> 3) Amplifier
> ------------
> R12 is indicated as "10W"

R11 and R12 are 10 ohms. I never noticed that before on R12 -thanks. That happens when you convert to .pdf and the translater fails to convert the special symbol. The omega symbol in the symbol font is the capital letter W. It just didn't get converted. 1/4W is fine.

Both resistors are optional. R11 helps those LM386 that like to motor-boat when the capacitor (C19) is not enough. Just forms a low pass filter to keep audio off the Vcc line. R12 helps cross-over distortion, but frankly, the regen action alone adds far more -hi.

> 4) Voltage Regulator
> --------------------
> You say that the drop across the forward biased LED1 is 1.3-1.8V,
> while across the Si rectifier D1 it's 0.7V.
> In series they'd sum up to 2 - 2.5V, but you also say that
> the voltage in the circuit is 3.0V, up to 1 V higher.
> Charles Kitchin's design fed the oscillator just 2.1V...
> Anything more we need to know? Would 2V be enough?

I have built several of these circuits with Kitchin's 3-diodes-in-series scheme with good results. The LED was added several years ago when several asked how would they add an LED to indicate power on. So I added the LED, using it as a "poor mans regulator" and the power on indicator to kill 2 birds with one stone. D1 raises this

voltage a bit, providing the lower voltage as the bias to the emitter follower, and affording some isolation between that bias and the regen bias, which knocked down some objectionable oscillations.

I apologize for the confusion in voltages. The DR2 has been documented and written about several times over the years, so discrepencies appear to exist. The batch of LED's I purchased for the kit drops 2.2v, making the total voltage almost 3v. Your mileage will differ.

One of the secrets of this regen stage, however, is the relatively low operating voltage. This is what keeps it from going into a wild regen oscillation like other circuits. The smoother regen action makes it much easier to control, holding in there over a wider frequency range, and makes it much nicer for AM detection. For this reason, this detector is not well suited for CW reception, as you never really get that "howl" type of regen oscillation.

Let me know if there are any other details I can help you with, and of course, I'm always interested in how others have built theirs. Due to having to postpone my plans to kit the DR2, the documentation never got completed and there are a few "holes" in it. I am hoping to get the prototype for the kit built before long, and when finalized, I will update the schematic, exact parts list and circuit description, including some drawings on how to build it "Manhattan Style."

> I thank you for your attention
> and hope you'll share some wisdom with us...

Likewise, let me know how you build yours on your end.

892. Re: Tuned circuit Q question

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-02-05 15:42:57 UTC
From: "William E. Sabin" <w.sabin@mchsi.com>
Message-ID: <5Q5Nd.49660$IV5.18534@attbi_s54>
Source record: 20525

The loading on the resonator is 1050 ohms in parallel with 5000 ohms, which is 868 ohms. A coil or capacitor reactance value that is 868 / 5 ohms (173.6 ohms) produces a Q of 5.

The initial value of L is

L = 173.6 / (2 * pi * 30MHz) = 0.92 uH

An additional loading is due to the resonator itself, which is the product of the coil Q times coil reactance.Let's assume a coil Q of 200. The resistance value of the coil itself is

Q * XL = 200*173.6 = 38720 ohms

The resistance loading by the capacitor can usually be neglected if it is very small.

The loading on the output side by the combination of the 5000 ohm load and the 38720 is 4428 ohms.

Go back to the beginning and get a slightly revised value of the resistive loading = 849 ohms that includes the loading by the coil itself. Recalculate L and C for this slightly different value of loading.

This iterative process can be stopped here.

Connecting the 50 ohm source directly to the coil through a 1000 ohm resistor produces an additional power loss which is equal to

20 * log[(1000+4428) / 4428)] = 1.8 dB.

This additional loss may not be acceptable in some applications. A low-loss coupling transformer (e.g. tapped coil) or low-loss tuned network is a better approach.

>-30mV 270megs.

How did you measure the resistance? Is it an incremental resistance
(slope of the V/I curve at the data point) or the slope of a line
joining the origin to the data point on the curve.
--
Regards, John Woodgate, OOO - Own Opinions Only.
The good news is that nothing is compulsory.
The bad news is that everything is prohibited.

Source record: 20526

Well. the 1050 ohm source in parrallel with the 5000 ohm load puts the resistance seen by the tank at around 867 ohms.

The circuit reactances would need to be RL/Q = 174 ohms.

I think you multiplied instead of divided. The calculations above assume that the Q of the elements that you use is large enough not to impact the calculations. You can calculate the equivilent parrallel resistance of the inductor you select, and add it in parrallel with the 867 ohms to assess the impact of a finite-Q inductor.

Don

And others where I used a transistor collector or JFET gate instead.

Pease Porridge in the Feb 3rd issue of Electronic Design mentions this problem, and Bob suggests using a transistor. "Using 2n3904s as diodes is very important because most ordinary diodes are much too leaky around +/-60mV to work well. Ordinary gold-doped 1n914s and 1n4148s are quite unsuitable..."

A diplexer in your case is merely a high pass and low pass filter connected at the common point. NO the Sat diplexers will NOT work....the cut off freq is wrong and they dont handle power well...
You COULD build one easily if you know the component values needed for the filters....but Larsen, Comet, Diamond and MFJ (which is the cheapest and most cost effective) all make one....You can get a MFJ 916B for about $30 bucks...and it will do what you need.

Yes if you use a serial resonant with a capacitor, inductor and a
resistor as you're suggesting you get voltage amplification factor
exactly equal to the Q of the circuit plus you get frequency and
bandwidth selectivity

With a transformer you get all 3 of the above without having to add an
inductor (as you use the inductors in the windings of the transformer)
plus you get impedance level shifting of the capacitance and
resistance in the secondary to the primary multiplied by the square of
the turns ratio multiplied by the capacitance and resistance in the
secondary of the transformer.
Is it worth it. I can't tell but I see more parallel resonant circuits
then serial ones .

I've actually seen implementations of the above using positive and
negative feedback circuits with an opamp to get some really interesting
results.

902. wire strippers

Newsgroup: rec.radio.amateur.homebrew

Anybody remember that cold head soldering iron advertised on tv
a while back? It was supposed to come with a pair of these
neat looking wire strippers. Well today at the Miami hamfest
someone was selling just the wire strippers. I got two of the
smaller ones good for .2-3mm wire (what's that in AWG?) and
one of the larger ones good for .2-6mm wire for $20.
These really are cool wire strippers, they quickly strip
any guage wire (in the supported range) without nicking the
wire. They even appear to work on some wire wrap wire that
is usually impossible to strip except with hard to find
'no-nick' brand cutters. (though you have to be carefull to
put the wire in the right hand side of the cutters where
the opening is a bit wider.

The www.icomamerica.com site will help with dealers.

AES and HRO do not appear to have anything in TX.

There is Texas Towers (which sells a full range of ham radio gear)
somewhere down there in Plano, but my Texas geography is a bit
sketchy. Not sure they have retail or just the online.

There are also Icom amateur radio dealers in Austin, Houston/Spring,
and Lubbock. It is possible that some of the land mobile Icom dealers
could help as well. Time to work the phone.

About the use of language: it is impossible to sharpen a pencil with a
blunt axe. It is equally vain to try to do it with ten blunt axes
instead.

Besides a mathematical inclination, an exceptionally good mastery of
one's native tongue is the most vital asset of a competent programmer.

I picked up a small wire stripper for a few bucks at a flea market, it works absolutely great on romex, 12 ga, 14ga, 18 ga. but not so hot on 23 - 24 gage wire with the high temp poly insulation. Kinda flattens it and tries to pull it off, but no dice. If you do a lot of work with big wire, these things are super.
Regards,
Tom

I haven't followed this thread very thoroughly, so this might not be directly relevant. But it should be of interest to anyone trying to detect small signals with a diode.

There are several reasons why diodes do poorly with small AC signals.

The first is, of course, the forward drop. However, this can in theory be reduced to an arbitrarily low value by reducing the current to a low enough value (by, for example, making the load impedance high enough).

The second is that the ratio of reverse to forward current increases as the signal gets smaller and smaller, reaching one at the limit. This can be observed by looking at the I-V curve of a diode. At the origin, the curve is a straight line -- the diode behaves just like a resistor.

The third reason is the diode capacitance. This shunts the diode, effectively lowering the reverse impedance. It also lowers the forward impedance, but when the forward Z is lower than the reverse Z, the net effect is to further degrade the forward/reverse impedance ratio.

You can make all the DC measurements you want, but they only tell half the story. When you apply AC, you charge the load capacitor during half the cycle according to the diode's forward impedance, and charge is removed from it during the other half according to the diode's reverse impedance. As the forward/reverse impedance ratio degrades due to the two effects mentioned above, the net charge you get in the load capacitance decreases, hence the voltage it's charged to decreases. This ends up looking like a larger diode forward drop.

I spent a lot of time thinking about this some years ago when designing a QRP wattmeter, and some of the conclusions I came to appear in the resulting article, "A Simple and Accurate QRP Directional Wattmeter", published in QST, February 1990. See the analysis on p. 20, "Ac v Dc: Why the Difference?"

This type of wire stripper is not new. What may be new is that it actually works. As I am sure all the old timers know, there was a wire stripper sold years ago that worked on the same principle: clamp and slide. Back in the late 60s when I started my first job, the lab had a number of them in the drawers. I tried them a few times. Sometimes they worked and sometimes they didn't. These were inflated-priced industrial quality. All the techs in the lab used the regular old Miller strippers. When adjusted properly, they were quick and reliable. We used No-Nicks for wire wrap wire. They were always reliable. I still have one. Not much call these days for wire wrapping!

I'd disagree. I know many very good commercial programmers who can't
spell to save their lives. But what really matters is that they can't
spell _consistently_, so mis-spelled variables and function names are
mis-spelled the same way every time (or the compiler catches the error
and they correct it to be consistent with their other mis-spellings).

It can be interesting reading some of the comments in their code!

Plus, of course, programming is not the hard bit- hasn't been for some time.
The skill lies in the system and software design. These days many packages
can autogenerate code and, with the high uP speeds and low memory costs,
that code is efficient enough to do the job- hand crafting to improve speed
etc often isn't required, even in real time apps. The move to the use of
real time operating systems has also reduced the demand for much of the core
software- one company can turn out versions (for example VxWorks, LynxOS)
that can serve many applications. The OEM manufacturer can focus just in his
particular needs, and pay a pitance of a fee to the RTOS supplier (sometimes
s few)

Tends to leave a lot of the old hacker types on the scrap heap- often as not
claiming everyone else is the hacker.

I do have a number of (likely) similar devices (Philips ,made in the Philippines) type ON4749 (green plastic enclosure with 7 gold plated pins/wires on a sturdy heatsink with 2 holes) ,which I have been unable to identify.
However they are physically identical to (also Philips) type BGY80 . This is a wideband module for Cable TV systems , 40 - 450 MHz, 12.5dB gain, max flatness +/- 0.2 dB ; output voltage 61.5 dBmV.

I'm looking for schematics for low power fm transmitters.
Power/stability is more important than range. I need a transmitter that
will transmit up to 50-100m (150-300 feet aprox.), but with a strong,
stable output in that range. I want to use it in conjunction with small
digital fm receivers. I regularly play paintball and a fm-com system
will give the team an edge :)
I would like it to be compatible with dinamic mics, because we want to
use throught mics (ala Tears of the Sun).

Any suggestions will be gratefully accepted.

Well, Mr. Anderson, thank you very much for your detailed reply. This all sounds very interesting but I think it's going to have a low benefit-to-work ratio, especially with the long project list I already have. I was hoping I could down to the passive re-radiator store and pick up something that you would work. Oh well.

Thanks again,

Vic

Simon,
Why worry about the extremely minute amount of radiation from small tuner coils and components when this is hopelessly swamped by radiation from the nearby antenna, even from the back of a beam, and there's always some significant amount from the feedline.

Think in terms of relative magnitudes.

The amount of radiation depends only on one dimension, ie., the physical LENGTH of what may be imagined to be radiating. Imagination is the keyword.

There is hardly any significant difference in radiation from a tuner between a plastic box, a metal box, and no box at all.

I prefer no box. Stray capacitance is smaller. A metal box behaves as a shorted-turn around the coils and results in power loss. And it's nice to be able to see the position of the roller coaster and the tuning capacitors without the tedium of unscrewing all the screws in the cover.

There may, of course, be a slight advantage of a box, metal or plastic, in a dusty atmosphere or if you are, like me, a nicotine addict.

Alcohol addicts will automatically ignore this mild advice anyway.

Reg, G4FGQ

This probably explains why instructions for installing and running
software are frequently inaccurate, misleading and leave out certain
vital steps. The criterion seems to be 'if it's close enough. it's good
enough'.

[snip]

Exactly. Well said Reg. I have seen a beautifully working 1KW antenna tuner constructed on a breadboard. Completely open and very nice to look at also. No TVI. No interference. Save yourself the hassle and expense and build it without an enclosure at all (as long as your pet cat doesn't like to wander around your shack while you operate!).

Shortcomings of computer programmers -

Lazy layabouts.

Lacking in logical thought.

A distinct weakness in use of the English language.

However, they are very good at outwitting their employers, who are even worse, and obtaining money (wages, salaries, fees) under false pretences.

Your article sounds interesting. Is there a link available to see it?.
The simplest approach I've seen, was is in the 'Levell TM6A broadband
voltmeter'(UK). Designer chopped the low level diode output at 20Hz,
allowing a 1mVac FSD.

Excellent description - thanks.

Only one small problem - as Win pointed out, Bob Pease feels a
diode-connected 2N3904 has lower leakage at low voltage than a 1N4148:

"What's All This Comparator Stuff, Anyhow?"

http://www.elecdesign.com/Articles/ArticleID/9517/9517.html

Does this mean a 2N3904 has a shallower slope than a 1N4148 through zero, or
perhaps one or the other has an offset, such as the Agilent Zero Bias
Schottky Detector Diodes shown in AN969?

http://www.spelektroniikka.fi/kuvat/schot8.pdf

Regards,

Mike Monett

Right. Take a look at a diode curve across a 100 uV region. Most diodes
will look pretty flat, even without considering the effects of
capacitance and other parasitics.

In other words, this data is just a plot of a diode's DC I vs V
characteristic, right?

What is of more interest is the slope at a given DC operating point. If
we pick 0V, for example, the above data (within the limits of its

precision) gives a flat line around that point (+5mV 21 Mohms, -5mV 21 Mohms). With a 100 uV signal, you might as well throw a 21 M ohm resistor in there instead.

Can't help with the MC's, however, the MPSH17's cross to NTE/ECG 229 and the
2N4417 is an NTE/ECG 452.
NTE and ECG replacement parts are very common just about anywhere. Your
local jobber will have them.
I have a hunch that the MC parts could be rounded up with a more exhausting
computer search.

No, it means its a better diode at low currents. See my curves again,
http://www.picovolt.com/win/elec/comp/diode/diode-curves.html Note the
1n458 and the JFET diodes, which follow the theoretical 60mV/decade rule
down to very low currents. As for Roy Lewallen's "ratio of reverse to
forward current" argument, there is no reverse current for these fine
fellows, at least for DC and reasonably low frequencies. It's the very
crummy gold-doped 1n4148 that falls over. Awwkk!

I tried one of the cassette audio couplers and now it will not exit!
Looks like I will have to remove the Philips car radio and take it apart.
The head had a small head-only plastic cover and this may have had to be
removed :-(

Exactly. At very small currents, the diode is just a resistor (shunted by a capacitance). At slightly small currents, it's a very poor diode, with reverse current almost equal to the forward current, so on each negative half cycle you suck out nearly all the charge you delivered during the positive half cycle.

Roy Lewallen, W7EL

Bill,
what I meant is that "when you want to make a coil with Q=200 - not
180 or 190" you may have to try some times if you haven't any
experience from which materials gives at least Q=200, a higher Q may
always be reduced to 200 with a resistor
Yes, I have a Radiometer Q-meter - quite old, almost as old as yours,
with thermionic tubes from the 30's and 50's, hi

Phil, not much call for wire-wrap? I still use it for all my
prototyping at work, my nixie tube clocks, all my home gadget
projects... I love the stuff. Of course it helps to have an electric
gun and a cut/strip/wrap bit!

I don't know what I'd do without wire wrap... anyone with wire-wrap
tools they don't want, I'll take 'em!

Terry.

Sure there is. All diodes have reverse current.

It's the very
> crummy gold-doped 1n4148 that falls over. Awwkk!

The gold doping is done to dramatically reduce charge storage time.
Without it, the voltage across a diode continues to be in the forward
direction for some time after you reverse the current through it. While
a non-gold-doped diode might look good in DC tests, it makes a lousy
rectifier of RF. In the extreme case, it acts like a PIN diode (which is
simply a diode designed intentionally to have a long charge storage, or
reverse recovery, time).

Alas, life is full of tradeoffs.

Hi Fella's
I am in the process of restoring an HW-202 back to as mint a radio as I can. I was able to get quite a few of them in various states of condition for very little money, and the idea is salvage all the really nice parts and make a perfect (close to perfect) radio for keeps. Well, this radio uses small male and female pin/plug connectors for the connection between the wiring harness and circuit boards and I would like to replace them with new ones preferably gold plated. Do you know where I could get an item like this? The originals look like they are tin plated and might become problematic with vibration and corrosion Or should I just use some sort of gold plated post instead and skip a removable pin/plug of the original? Thank you in advance for looking this over for me.

Best wishes

Terry, we use millions of dollars worth of design and simulation
software to do our prototyping at work. The only tools we handle are a
keyboard and a mouse. If we are REALLY lucky the $5 million dollar ASIC
works out of the shoot. More likely, we need to spend a couple more
million to re-spin the design to get rid of a few really obscure bugs.

Back in the good old days, we could easily add/remove wire wrap wires on
the prototype backplanes until the pesky obscure bugs were squashed. Ah,
for the simpler days!

I need to clarify this. My comments apply only to junction diodes, which virtually all silicon diodes are. Schottky diodes don't exhibit this charge storage effect. That's one reason they're often used in high frequency switching supplies. Their leakage current is, however, much greater than silicon diodes.

I bought my first set of these strippers at Home Depot.

For the record, I got a cold heat soldering iron (including a second
set of these strippers) for Christmas and y'know? It works pretty darn
well. I don't use it as my every day soldering iron, but you can bet
it will be in my tool box when, for example, I take my combat robots to
competition. The trick to them appears to be be *gentle* with the tips.

Hi Ed,
I went through the whole thing with Doom Electronics when I was
trying to buy some SL6440s. This company will only sell to other
dealers.....not to manufacturers or to private individuals. Doom did
hook me up with a jobber who would sell me a minimum quantity of 25.
Too bad Motorola discontinued these devices.....now you have all of
these entities selling for more than the devices originally sold for.
Fortunately, a friend of mine located one of the jobber's sources, and we
were able to buy them for 1/3 of the jobber's price.

> What are the collectives thoughts on the type of material to use for a
> homebrew ATU enclosure, should it be aluminium to reduce unwanted RF
> radiation or plastic to reduce coupling effects possibly caused by an
> aluminium enclosure.
==========
For QRP power levels it could be best fitted in a wooden box , simple and
easy .
For much higher power levels a metal enclosure will be better.
However ,in order not to influence inductances by the metal cabinet , a rule
of thumb says that (air) inductors should be free form any metal keeping a
distance of their diameter
Example : With a fixed air or roller inductor of say 100 mm (4 inches)
,you need an enclosure of at least 300 mm (12 inches) such that the inductor
is not less than 100mm from any metal surface.

For this reason many homebrew antenna matching units are fitted inside
non-metallic enclosures often made of perspex (plexy glass)

I'm not sure what you mean by an "offset" -- all diodes cross through the origin of the I-V curve, when excited by DC, anyway -- unless they contain a battery. In the reverse direction, the current pretty much levels off beyond a small reverse voltage. The current of this level part is the saturation current.

Again, don't think that good DC characteristics make for a good RF detector. A number of other factors, which have been discussed here, are very important. As I recall, only transistors designed as saturated switches (2N918 comes to mind, but it's been a long time, so don't quote me) are gold doped. Ones which aren't, and I'm quite sure the 2N3904 is in that category, will have long reverse recovery times so will make poor RF rectifiers. Circuits became too fast for saturated switches long, long ago, so I'd be surprised if gold doping is done any more except for replacement transistors in very old equipment.

You can learn a lot with a very simple setup consisting of nothing more than a variable amplitude signal generator, a diode, load resistor and capacitor, and a meter or scope. SPICE should also show these effects provided you use good models.

I am trying to use a local oscillator board from an old Motorola UHF FM radio as part of a microwave construction project. I need to know the input impedance of the multiplier chain so I can design a new crystal oscillator/buffer. The original crystal frequency is in the 18 MHz region but the input coils on the board tune at around 54 MHz so obviously there is a tripler inside the channel element.

Does anyone understand how Motorola did these things ? The original channel element is a TLN 8968A - anyone got a schematic ?

73,
Steve VE3SMA

Don't people still use 2N2369As, or at least the plastic version?
If not, what do they use instead?

(Does gold doping work for PNP transistors? I don't see why it wouldn't,
but I've never seen a specific reference to a gold-doped PNP.)

No. Doping "sex" (of gold) is wrong for the N-type base, which is
where you're trying to induce recombination.

When I needed diode clamps that would work with +/-100mV with less than 10pA of leakage, I always used selected Jfets with some back bias. The DPAD10, etc. series of diodes that were designed for this were too expensive. But that was when I was at Fluke and I could specify exactly what I wanted and the vendors would come knocking. Most of the parts were specially selected from National process 50, which was used to make 2N4416 RF transistors.

The diode equation works over all ranges of the diode. We also used 2n2484 over 9 decades of current (pA to mA) of DC and tested them to be very log-linear. At AC, as already stated, you have to include the capacitance in the model. A finger print on the transistor body would ruin the response.

At 1000 -1500 Watts RF it is better to keep thing within metal walls.

As I understand it ,in the USA any amateur radio station operating at an RF power level in excess of 50 Watts needs to make a 'antenna radiation assessment'
Although an antenna matching unit is not an antenna , sitting close to a non-screened matching unit with air inductors operating at 1000 -1500 Watts RF output ,seems to me rather too close for comfort.
For the same reason RF power amplifiers (even when home brewed) are no doubt inside a metal enclosure.

==========

The problem lies mainly in the imagination. What measurable harm can befall
you?

A coil of wire in a tuner radiates hardly more than a straight length of
wire of about the same length as the coil former.

Radiation is negligible in comparison with the field from the nearby
antenna, even from the back of a beam, which nobody worries about.

Reg.

Well, I can certainly imagine being zapped by high RF voltages!

Of course, that's not the real subject of this thread, but it's
certainly a reasonable practical consideration.

I wonder, if there's a solid material, suitable for construction of an
enclosure, whose electrical properties are more similar to that of air
than those of metal or wood?

Yes, the PAD-1 and pn4117 JFET curves on my plot show your point,
http://www.picovolt.com/win/elec/comp/diode/diode-curves.html
with about 150 to 200mV forward voltage at 1pA. In that setup,
the current for under 100mV was well below what I could detect.

Not to mention the long reverse-recovery time of those parts. I put
up my graph to counter Dave's claim of a 600mV "barrier potential",
not to argue that these diodes make good low-level RF rectifiers. :>)

Digikey stocks Panasonic 2kV capacitors up to 5600 pF (= 0.0056 uF).
See, for example, part number P4495A. Two or four of these in parallel
and you're set.

Tim.

986. The Definitive Chord & Scale Bible - Literally EVERY chord and scale!

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-02-08 17:51:29 UTC
From: Kind of Blue28 <createbeforeyouhate@itsjustabook.com>
Message-ID: <2005020809512994992%createbeforeyouhate@itsjustabookcom>
Source record: 20419

Finally it exists!! IF YOU PLAY GUITAR, YOU NEED THIS BOOK!! Listen to my story:

In the process of teaching myself guitar, I went looking for a book that simply had the all the chords, scales and modes, and nothing else. I was totally surprised to find that such a book didn't exist. There are plenty of places to find this information, but it tends to be spread out over the coarse of a long book or in a poorly organized workbook. I found some of it on the web in the form of calculators and such, but that wasn't helpful since I wanted to practice away from my computer. That is why I created THE ULTIMATE GUITAR RESOURCE, which has LITERALLY EVERY CHORD, SCALE and MODE in an easy to download and print document. Its a full 37 pages for only $3.99! (hardcover is available)

What makes this guide even better is that you don't need to read music to use it, so it can help every player at any level. I guarantee you'll use this guide for years!

For way less than you spent on lunch, you'll learn:
-EVERY CHORD (in every position)
-EVERY SCALE, including the jazz and blues scales
-ALL THE MODES
-LITERALLY EVERYTHING YOU NEED TO KNOW - solo and play chords without reading music today.

A free sample is available at:

<http://keystone-music.com/>
<http://keystone-music.com/>
<http://keystone-music.com/>

Good luck and God Bless!

p.s. I apologize if this message annoys, aggravates, miffs, disturbs, bugs or angers you. I'm actually just a dude who wrote a book that hundreds of people are using and apparently liking very much. While this may fall into a spam-like category, (since I am selling something, and you didn't ask for this message), I think that its not totally over that line since I'm not pitching a porn site, a refinance loan or a cock enlargement.
Peace!

========================

If you insist on an enclosure, next to wind, why not try glass?

Then you can view the roller and capacitor settings without the inconvenience of taking all the screws out of the cover. It's also easy to show a next door neighbour the works, calm him down, just after you've cleared his TVI.

There's only roughly 1000 volts, its RF not DC, around a 1 KW tuner. Fairly harmless stuff. You can't call yourself a real ham unless you've ever had to quickly remove the tip of your forefinger from a hot spot.

But don't make a habit of kissing capacitor vanes, attractive as they are, because they look beautiful in motion!

Reg, G4FGQ

I don't know about the ww wire where you are, but the cheap manual wrapping tools that Radio Shack used to sell work fine for stripping here, they had that built in hole with a sheet metal plate with an angled slot that you just pulled the wire into then pulled the wire down. I wrapped many a board with just that tool, I never did like the power wrapping tools I bought. I also didn't like the manual tools that held the spools of wire that you didn't strip since they wrapped tight enough that the posts cut thru the insulation.

Of course this is a hobbyist view, if I had to wrap dozens of boards a day instead of one every couple of months I'm sure I would have a differenet opinion of wrappers.
thanks, John.

I don't know about the availability of them in SA, but as someone else mentioned FRS radios are both cheap and small. I used them here, the vox headset would fit under a mask and you just had to clip the radio somewhere where you wouldn't smash it too much (those stubby antennas take a pretty good pounding before they break off). Range is up to around a kilometer in more open terrain, down around 100m used inside buildings. Be aware that a week after you start using them, your opponents will have at least one to listen in on your team comms.

The trick then is to have a code system that your players use to refer to objects and players.

It isn't enough to just wear them at the paintball field during games, you need to practice with them on, since some people have trouble following directions over the radio in the heat of combat, they just tune out the radio and concentrate on what they see in front of them.

Here in the US you can get FRS radios in the $10 range, cheap enough that even losing one (when someone hits the dirt and lands on it) is no problem. Vox mikes will be more than double that, and I haven't seen throat mikes, though I have seen earbud mikes like they sell for cell phones. If you really get into it, a mike and speaker could easily be built into the face mask for each player, and I am sure it would be cheaper than buying boom headsets like we used or throat mikes and earpieces like you are thinking of using.
thanks, John.

>but I've never seen a specific reference to a gold-doped PNP.)
Without going into the details of Quantum chemistry and electronic
configurations (which is certainly more challenging and exciting) you
can easily see it from a simplified perspective of the energy bond
model of semiconductors.
For a npn transistor doped with Gold the equilibrium density (ed) for
impurity electrons in Silicon doped with gold is given by the well
known Fermi-Dirac statistics equation.
ed = B*Nd*exp(-Edonors/kT) E donors is the energy required for Golds
electron to freely dwell in the Silicon lattice ... a value much
smaller then the E gap energy value for Si to create an electron hole
pair.
Smaller values of Edonor imply larger values free donor electrons.

If a pnp transistor was to be formed from Si doped with Gold the
equilibrium density (ph) for impurity holes in Silicon doped with gold
is
ph = A*Na*exp(-Eacceptor/kT) Eacceptor is the energy required for a
electron to be stripped from the Silicon atom by the Gold atom.

As Eacceptor is greater then Edonor only a npn transistor can be formed
from Si doped with Gold.

Its even more exciting to look at the Physics of Gold plated
transistors. Very intriguing .. just like the MOSFET transistor!

The only good way to wire wrap is with the battery operated
tool with the bit inside the sleeve. (Gardner-Denver)
The self stripper tools
had to be used with special wire that stripped easily.
BTW I have this huge spool of teflon insulated ww wire (30g)
that is real tough to strip. Got it surplus.

1001. MW phase and amplitude trimmer?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-02-10 12:09:39 UTC
From: Ron Hardin <rhhardin@mindspring.com>
Message-ID: <420B4F0F.20AE@mindspring.com>
Source record: 20434

I have an 8-element MW active array (DA100E's and ALA1530's) spread out
over the yard and combined in 7 ANC-4's

I need a way to put a slight phase shift and amplitude shift on
one (or more) of the inputs, because when you're down in a 60dB
null, fraction-of-hair turns of the ANC-4 pots become necessary.

At the moment, I add another ANC-4 to another element at very very low
gain and use it as the final trim, but that produces a 3dB loss in
signal too.

So I want a passive box on one of the inputs instead, where turning
a couple of knobs will produce a _slight_ shift in phase and in
amplitude (they can couple but have to have two degrees of freedom).

I was thinking of a capacitor in series, and a pot voltage divider
selecting the main output and a tiny bit of the capacitor output,
for one; a straight voltage divider pot for the other. Pots in
parallel with small resistors to make them have very little effect.

Then, I was thinking, I could get close to a null with the ANC-4's,
and then finalize it with the trimmers.

Any suggestions? Better ideas?

Source record: 20437

I know where to find good reduction drives
and calibrated SMD knobs
for 1/4' shaft variables and pots...

BUT

...I have never found any ready to buy
scale disk or pointer to mount on a 1/4" shaft
of e.g. caps with built in reduction drives.

These must allow the shaft all the way through
so a knob can be mounted on the tip of the shaft.

When I needed one, I drull (*) through a regular knob and superglued a
disk or aluminum hand to the bottom of it, and quite disliked it.

I saw this kind of pointers on several kits etc.
and if reduction caps exist,
pointers or scaledisks must exist too,
but where can I buy some?

TIA

Filippo / SpamHog
http://filippo.ru.ru

(*) I like to hack up radios, but I also like to mod my verbs. "to
drill" sounds so much better in the irregular "to drill, drull, drult"

When I used to work for an engineering firm, we used to prototype in
wirewrap. Generally, we'd wrap up a handful of modules for testing.
Production would be properly soldered boards (I once assembled 200 of
'em myself when we were in a pinch.) This was almost all digital
electronics, but a fair amount of the control was discrete parts (we had
a lot of buffers and drivers, since this stuff talked to 500v grain
elevator hardware), with an EPROM running the show.

We found the only way to maintain a prototype over weeks was with tight, self-stripping connections. Mostly because we ended up unwrapping things a fair amount, and then re-wrapping with fresh connections. We tried the simpler tools that you strip by hand, but they kept losing the mechanical connection to the posts after a few weeks of digging around and re-wrapping, which caused spurious and hard to diagnose problems. Once we switched to the right post and wrap combo, things were much easier.

Obviously, this is about using the right tool for the application. I haven't wrapped wire in years, so at this point I'd be likely to stick it in my eye or something.

1008. Re: HW-100 - 12 volt filament mod for 6883 finals

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-02-11 19:31:46 UTC
From: Antonio Vernucci <vernucci@tin.it>
Message-ID: <CK7Pd.876608$35.33251735@news4.tin.it>
Source record: 20441
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.boatanchors

I do not know the HW100, but for the HW101 I have using 6883s should be no problem. If you put on paper the filament circuit you will easily realize that putting the final tubes in parallel instead than in series makes no change for the other tubes.

I have the schematic of the HW-101, which succeeded the HW-100 but is basically the same. The 6146 heaters are in series, so with a little rewiring, 6883s can be used.

But be sure to mark the rig to show that this mod has been done, because if at some future time someone puts 6146s in, they'll be toasted.

Good lord, what a Goldburg way of doing things.

Use one transistor in a phase-shift oscillator configuration and chose
your components for the same waveform ;-)

Won't work. He has the amplitutude ramping up and down at the beginning and
end of the tone.

The same thing could be done digitally by a fast microcontroller. I think it
would be quite easy with a software DDS.

While you may not get the same effect or knowledge of building the circuit
there are some ICs that will do that in one small package.
Even the one transisitor oscillators are good enough for learning the code.

==========
Indeed a single transistor 'double Tee' phase shift oscillator with a single
chip audio amp ,if you wish to use a loudspeaker , + a key is all you need
to learn /practice morse code.
It is a popular 'very simple project' candidates for the UK Intermediate
Licence can choose to do .
At the moment candidates for this AR licence have to construct something
simple in order to be assessed for basic construction/soldering skills.

Hi Leon!

Sure will, I've done it....by accident ;-)

Had a slow-starting conventional phase-shift oscillator once and decided
to "fix it".....ended up using the "flaw".

Changed the oscillator and adjusted the Re so you get a nice shaped rise
on the leading edge, cap from keyside to ground gives you the lead-out and
a little 1N4148 in the base-bias keeps her stable across room temprature
range from 15 to 25C.

IIRC, the xsistor I used was a 2N5088, replacing the existing 2N2222 for
more gain control.

Any method of locally generating the Morse characters are OK for
learning the Morse code.

>It is a popular 'very simple project' candidates for the UK Intermediate

According to the ITU-R recommendations, including the third harmonic
(for non-fading circuits) or even the 5th harmonic (for non-fading
circuits) is enough. For 12 WPM, this would translate to 30 or 50 Hz
bandwidth.

Why should any CW enthusiasts be encouraged to use any emissions
broader than this ?

As 6146's became expensive hams started using 6883's which were cheaper
but now the 6883's cost as much as the 6146's. If you are not using
the rig mobile and can fit a 1:2 or 1:4 step up transformer under
the chassis you can also find 6159's a little cheaper. These are
the same as 6146's but with 25 volt heaters. The 6159 was mostly
used in aircraft radios and is available military surplus.

Good News!

Do you know how simple it is to go to Heaven after this life has ended?

The good news is that God came from Heaven to earth in the person of Jesus Christ over 2000 years ago and died for our past, present and future sins(misdeeds). He was born in the land of Israel supernaturally to a virgin Jewish woman named Mary. He lived a sinless life for thirty-three years and then sacrificed His sinless blood and died on a cross to pay the death penalty for our sins.

After Jesus died He rose from the dead three days later as He said He would. The Holy Bible also tells us that Jesus Christ ascended into Heaven and that all who accept Him as their Lord and Saviour will live forever with Him in Heaven where there is no more death, sorrow, sickness and pain.

The Holy Bible very clearly explains how simple it is to be saved and on your way to Heaven, "For if you confess with your mouth, "Jesus is Lord," and believe in your heart that God raised him from the dead, you WILL BE SAVED." (Romans 10:9)

You can be saved right now and on your way to Heaven if you will open your heart to Jesus and pray the following prayer:

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven when I die. I agree with You that I am a sinner. I believe You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins. I believe that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thank You Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

You are now a Christian if you said the prayer and allowed
God to save you. Welcome to the family of God.

If you decide to wait till later you may die before you get
another chance to be saved because none of us knows
exactly when we will die.

Have a great day!

G3TQD modified his HW100 so we could operate RSGB national field day
within the rules, and put a PL36 into the PA instead of 2x 6146B's.
Operated the whole contest with at least 120W input with no problems,
so I would believe it is many alternatives which are not exact
equivalents but will work fine

I was just wondering if anyone out there might have a schematic of an amplifier using a single 4-400 tube in grounded grid configuration that they might have constructed or even a website with one? It doesn`t have to have tuned input or power supply with it. I can do the math and figure out values for it, but thought I might check and save myself some time. Thanks for any info, Rob WB8VWI

==========
An RF Power amp. for the HF bands with 2 4-400's in grounded grid
configuration can be found in ARRL Handbook 1986 , pages 30-40 and 30-41.
Input circuit is very simple ,perhaps too simple for a solid state front end
transceiver.
In the old days with valve transceivers having their own PI tank tuning
,this was acceptable.
Suggest you also have a look at AG6K's web site which has a lot of info re
RF power amplifiers with valves.

Greetings,

A while back, I was browsing the newsgroups, just like you are now, and came across an article similar to this that said you could make thousands in CASH within weeks with only an initial investment of $6.00 (American) plus International stamps due to users that may be outside the United States! So I thought, "Yeah, right, this must be a scam!" But like most of us I was curious and kept reading. It said that if you send $1.00 to each of the 6 names and addresses listed in the article, you could make thousands in a very short period of time. You then place your own name and address at the bottom of the list at #6, and post the article to at least 300 newsgroups. (There are about 32,000 of them out there and that's quite a large market pool). No catch, that was it. Even though the investment was a measly $6, I had three questions that needed to be answered before I could get involved in this sort of thing.

1. IS THIS REALLY LEGAL? I called a lawyer first. The lawyer was a little skeptical that I would actually make any CASH but he said it WAS LEGAL if I wanted to try it. I told him it sounded a lot like a chain letter but the details of the system (SEE BELOW) actually made it a legitimate legal business.

2. IS IT OK WITH THE POST OFFICE OR IS IT MAIL FRAUD? I called them: 1-800-725-2161 and they confirmed THIS IS ABSOLUTELY LEGAL! (See 18, sections 1302 NS 1341 of Postal Lottery Laws). This clarifies the program of collecting names and addresses for a mailing list.

3. IS IT RIGHT? Well, everyone who sends me a buck has a good chance of getting A LOT of CASH ... a much better chance than buying a lottery ticket!!! So, having these questions answered, I invested EXACTLY $8.22 ...

six $1.00 bills and six 37-cent postage stamps ... and boy am I glad I did!!! Within 7 days, I started getting CASH in the mail! I was shocked! I figured it would end soon and didn't give it another thought. But the CASH continued coming in. In my first week I made between $20 to $30. By the end of the second week I had made a total of $1,000.00. In the third week I had over $10,000.00 and it was still growing. This is now my fourth week and I have made a total of just over $42,000 and it's still coming in..... It's certainly worth $6.00 and 6 stamps!!!

Also, make sure you print a copy of this article NOW, so you can get the information off of it, as you need it. I promise you that if you follow the directions exactly, that you will start making more CASH than you thought possible by doing something so easy!

Suggestion: Read this entire message carefully! (Print it out or download it.) Follow the simple directions and watch the CASH come in! It's easy. It's legal. And, your investment is only $6.00 (Plus postage), IMPORTANT: This is not a rip-off; it is not indecent; it is not illegal; and there is virtually no risk - it really works!!!! If all of the following instructions are adhered to, you will receive extraordinary dividends. PLEASE NOTE: Please follow these directions EXACTLY, and $50,000 or more can be yours in 20 to 60 days. This program remains successful because of the honesty and integrity of the participants. Please continue its success by carefully adhering to the instructions. You will now become part of the Mail Order business. In this business your product is not solid and tangible, it's a service. You are in the business of developing Mailing Lists. Many large corporations are happy to pay big bucks for quality lists. However, the CASH made from the mailing lists is secondary to the income that is made from people like you and me asking to be included in that list. Here are the 4 easy steps to success:

STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen

through the envelope (to prevent thievery). Place one paper in each of the 6 envelops and seal them. You should now have 6 sealed envelopes, each with a piece of paper stating the above phrase, your name and address, and a $1.00 bill. What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it! Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office (1-800-725-2161) and they confirmed that it is indeed legal! Mail the 6 envelopes to the following

addresses:

#1) Brian King 15O'Dea Pl St.Johns NL canada A1c 3c6

#2) D. Ben Istomin, 2530 Betsy Way, Rancho Cordova, CA 95670

#3) D. Gardner, 5808 San Pierre Ct., Bakersfield, CA 93308

#4) Eduardo Rodrigues, 404 N. Montello St. #3, Brockton, MA 02301

#5) Darlene Rodrigues, 1 Madrid Square #4, Brockton, MA 02301

#6) Jay Conway, PO BOX 1116 Lake Sherwood, MO 63357-1116

STEP 2: Now take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the list.

STEP 3: Change anything you need to, but try to keep this article as close to the original as possible. Now, post your amended article to at least 300 newsgroups. (I think there are close to 32,000 groups) All you need is 300, but remember, the more you post, the more CASH you make! This is perfectly legal! If you have any doubts, refer to Sec. 18 1302 NS & 1341 of the Postal lottery laws. Keep a copy of these steps for yourself and, whenever you need CASH, you can use it again, and again.

PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by them carefully adhering to the directions. Look at it this way. If you are a person of integrity, the program will continue and the CASH that so many others have received will come your way. NOTE: You may want to retain every name and addresses sent to

you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.) So, as each post is downloaded and the directions carefully followed, six members will be reimbursed for their participation as a List Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousands of CASH in CASH!!! What an opportunity for only $6.00 ($1.00 for each of the first six people listed above) Send it now, add your own name to the list and you're in business!

---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS----------

Step 1) You do not need to re-type this entire letter to do your own posting. Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this letter, and select 'copy' from the edit menu. This will copy the entire letter into the computer's memory.

Step 2) Open a blank 'notepad' file and place your cursor at the top of the blank page. From the 'edit' menu select 'paste'. This will paste a copy of the letter into the notepad so that you can add your name to the list.

Step 3) Save your new notepad file as a .txt file. If you want to do your postings in different settings, you'll always have this file to go back to.

Step 4) Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, message boards, chat sites, discussions.)

Step 5) Visit these message boards (Best way to find them is use a search engine, type in " news groups + free message posting") and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button. You're done with your first one!

Congratulations...THAT'S IT! All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup!

REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE CASH YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 300

That's it! You will begin receiving CASH from around the world within days! You may eventually want to rent a P.O. Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it. **JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.**

Now the WHY part: Out of 300 postings, say I receive only 7 replies (a very low example). So then I made $7.00 with my name at #6 on the letter. Now, each of the 7 persons who just sent me $1.00 make the MINIMUM 300 postings, each with my name at #5 and only 7 persons respond to each of the 7 original 7, that is another $49.00 for me, now those 49 each make 300 MINIMUM posts with my name at #4 and I get 7 replies each, I will bring in an additional $343.00! Now, those 343 persons turn around and post the MINIMUM 300 with my name at #3 and only receive 7 replies each, I will make an additional $2401.00! OK, now here is the fun part, each of those 2401 persons post a MINIMUM 300 letters with my name at #2 and they each only receive 7 replies, that just made me $16,807.00!!! Those 16807 persons will all deliver this message to 300 newsgroups with my name at #1 and if 7 persons per 300 Newsgroups react I will receive

$117,649.00! With an original investment of only $6.00! And some stamps. AMAZING! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $6.00 to names on the list, putting your name at number 6 again. And start posting again. The thing to remember is: do you realize that thousands of people all over the world are joining the internet and reading these articles everyday? JUST LIKE YOU are now!! So, can you afford $6.00 and see if it really works?? I think so... People have said, "what if the plan is played out and no one sends you the CASH? So what! What are the chances of that happening when there are tons of new honest users and new honest people who are joining the internet and newsgroups everyday and are willing to give it a try? Estimates are at

20,000 to 50,000 new users, every day, with thousands of those joining the actual internet. Remember, play FAIRLY and HONESTLY and this will really work. By the way, if you try to deceive people by posting the messages with your name in the list and not sending the CASH to the rest of the people already on the list, you will NOT get as much. Someone I talked to knew someone who did that and he only made about $150.00, and that's after seven or eight weeks! Then he sent the 6 $1.00 bills, people added him to their lists, and in 4-5 weeks he had over $10k. This is the fairest and most honest way I have ever seen to share the wealth of the world without costing anything but our time!!! You also may want to buy mailing and e-mail lists for future CASH. Make sure you print this article out RIGHT NOW! Also, try to keep a list of everyone that sends you CASH and always keep an eye on the newsgroups to make sure everyone is playing fairly. Remember, HONESTY IS THE BEST POLICY. You don't need to cheat the basic idea to make CASH!! GOOD LUCK to all and please play fairly and reap the huge rewards from this, which is tons of extra CASH. Please remember to declare your extra income. Thanks once again...

"People have asked me if this is really legal. Well, it is! You are using the Internet to advertise your business. What is that business? You are creating a mailing list of people who are interested in home-based computer and online business and methods of generating income at home. Remember, people send you a small fee to be added to your mailing list. It is legal. What will you do with your list of thousands of names? That's up to you."

So, build your mailing list, keep good accounts, declare the income and pay your taxes. By doing this you prove your business intentions. Keep an eye on the newsgroups and when the cash has stopped coming (that means your name is no longer on the list), you just take the latest posting at the newsgroups, send another $6.00 to the names stated on the list, make your corrections (put your name at #6) and start posting again.

NOTES: *1. In some countries, the export of the country's exchange is illegal. But you can get the license to do this from the post office,

explaining the above statements (that you have an online business, etc. You may have to pay an extra tax, but that's OK, the amount of the incoming CASH is HUGE! And as I said, a few countries have that restriction. *2. You may want to buy mailing and e-mail lists for future CASH. (Or Database or Spreadsheet software.) *3. If you're really not sure or still think this can't be for real, please print a copy of this article and give it to someone who really needs the CASH, and see what happens. *4. You will start getting responses within 1-2 weeks.

ALSO REMEMBER SEND YOUR $1 OUT TO EVERYONE ON THE LIST, EVEN IF THEY ARE NOT FROM THE U.S. BY DOING SO, YOU'RE EXPANDING YOUR BUSINESS TO THE ENTIRE WORLD AND SECURING YOURSELF AN EVEN LARGER INCOME. WHAT ARE YOU WAITING FOR??? $$$!!! $$$!!! $$$!!! $$$!!! $$$!!! $$$!!! $$$!!! $$$!!! $$$!!!

GOOD LUCK!!!

1033. Minimal "Chassis" size for HB rig?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-02-14 19:15:32 UTC
From: "Airy R.Bean" <Me@privacy.net>
Message-ID: <37cbsuF56al3iU1@individual.net>

Much of the negativity that the CBer-Masquerading-As-A-Radio-Ham emits when it is suggested to him that he should build his own rig comes from a complaint that it is not possible to miniaturise a rig to the sizes that are available from the Nipland CB suppliers, mainly Yaesu and Kenwood.

But, surely, the size of a rig is irrelevant to anyone interested in technical
performance?

I wonder what size of rig is really acceptable to the _REAL_ Radio Ham when you consider that the RACAL RA17 was a large 19" rack model, and
when you take into consideration the footprint of desktop PC's that have been welcomed so recently into a number of shacks?

How about a foot print of between 12" and 18" square, with a height of about 3"?

That would make a rig about the same size as a DVD player, again, an item of consumerist products that until recently was unknown but now is de rigeur - again
pointing out the spurious argument put up against HB.

In a box 18" square by 3" tall, we'd have enough room to manoeuvre and to experiment with circuit changes but without worrying that our Henley "Solon" soldering irons were going to melt a component other than the one we're currently dealing with.

Give me a steel chassis - 3' wide and 2' deep, with a 20 lb power
transformer, a 15 lb modulation transformer, a 5 lb audo output
transformer, and a dozen or so octal based tubes.

----- or, a BC-610 and an HRO-50.

Er why not. It's doable as a homebrewer. My favorite chassis is old
cb rigs. outercase subcase and front pannel are often useful. Even
put a 6m sideband rig in one.

>But, surely, the size of a rig is irrelevant to anyone interested in
>technical performance?

Most appliance ops dont understand perfomance.

>I wonder what size of rig is really acceptable to the _REAL_ Radio Ham when

Boat anchor. Good radio and small for that time. They still do not
go cheap.

>How about a foot print of between 12" and 18" square, with a height of about
>3"?

That is a bit big. The usual footprint I shoot for is 2" tall by 6"
wide and maybe 8"deep. That's 96 cubic inches, plenty of room.

Allison

and just where do you intend to buy all those components from
after youve searched and found that there are only a few places and the
all charge the earch for a resistor or a transistor the cost of building a
Tranciver is prohibitive
its far cheaper to modifie existing stuff to the bands you want to use ie
11mt to 10mt to 6 mt
just my opinion
but then again in true amateur status i never buy anything i just loan it
from work or rescue it carefully from the skip where it was carefully
placed ;)
sonow you know where all those LED's came from

I'm currently building Pic-a-star, and haven't given the final casing a thought yet. Rather than trying to build to a pre-determined size, I'll design the case around whatever size the radio ends up, allowing for 'poke-about-a-bility' when it's done.

I don't find the SMT devices a problem. G3XJP has come up with some excellent ideas for repeatable, reliable methods of using them. By making the code open-source, it is also encouraging to have a dabble, and see what changes when certain parts are altered. A true homebrewer's delight!

There is a chap locally (G8SUY I think) who has developed some ATV SMT
designs- they seem to work well and be popular. If you can hold the parts
while soldering then SMT isn't too bad- an illuminated bench magnifier
helps.

Sadly, I'm sure someone will come along and falsely claim G3XJP's code was
hacked and needs rewriting- totally ignoring his efforts to encourage
homebrew and failing to produce anything to replace it.

1039. Something like a diplexer

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-02-15 00:51:45 UTC
From: Joel Kolstad <JKolstad71HatesSpam@Yahoo.Com>
Message-ID: <faudncsAR8Q32ozfRVn-3w@comcast.com>
Source record: 20372

I'm trying to build a circuit to split two signal paths apart, process them differently, and them put them back together. In particular, I have incoming RF signals from ~25MHz-3GHz (they're going to a wideband receiver) and I have some notch filters that I want to be able to selectively engage between 25-500MHz.Due to the topology and parasitics of the filters, they tend to roll off above 500MHz and have significant loss by the time you get to 3GHz.

Hence, I'd like to run 25-500MHz though one signal path and 500MHz-3GHz through another (I want to leave the 500MHz-3GHz part untouched). The 'cross over' region doesn't have to be particular 'clean' (i.e., it can vary +/-5dB easily).

I tried desgining a 5th order diplexer, and it cleanly splits the two frequency ranges into separate path going to their own terminators. However, if instead of terminating the low pass output and high pass outputs to their own loads I connect the two outputs together, I get something of a mess -- not at all a 'flat line' like I was hoping for.

I next tried hooking up two of these diplexers 'end to end,' and while the response is almost flat, it has a very sharp null right at the 500MHz corner frequency, and another very sharp set of nulls a couple hundred MHz above and below this (they're mirror images). Hmm...

So... any hints how to do this properly? I thought for certain the end to end diplexers would have done the trick.

Thanks,
---Joel Kolstad

To split a signal you can use a direction coupler.
I have seen "hybrid" ring models made of transmission line with specific length in UKW-unterlage A4 typed edition 1980's.
To inject a signal you can use a direction coupler too....
>and them put them back together.
Maybe Google for Dubus artikels.
I'am just giving a hint.
A piece of thick coax, braid a wire for about 1/4 wavelength under the outer layer, remove plastic cover first.
Connect one end to a resistor 50 Ohm (same as the transmission line impedance) other end of the resistor to earth.
The other end of the wire to get signal from or put signal in.
Idea from the book antennenbibel Karl Rothammel.

1041. Linux and X-Windows

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-02-15 03:09:07 UTC
From: "Leland C. Scott" <k.c.8.l.d.o.@arrl.net>
Message-ID: <_e2dnU1Uk8JJ-ozfRVn-og@comcast.com>
Source record: 20374

I received the following E-mail from Paul Swart (pauls@starnet.com) at Starnet Communications about a special license fee for their X-Win32 client software for running Linux X-Window desktop, and apps, remotely over the Internet or a LAN connection. I would think there would be some Hams who would be interested in contacting Paul about his proposal.

http://www.starnet.com/products/

I've tried the demo out using the Gnome desktop under Fedora Core 3 and it's a really slick bit of work.

-
"How many of these non-commercial Ham users would you say could use the X-Win32 X server?

I'm thinking about setting up some kind of special (low-cost) license program exclusively for this kind of use by Ham radio operators so cost would not be any barrier. Just like we're selling lots of classroom/lab licenses to schools at around $30. The revenue basically supports our cost of the program, including the engineering and tech support we provide to these users. I'm sure you have ways to make this known to others in your Ham community so that the volume would justify putting the program in place."

Let me now if I'm onto something or whether we're talking about a handful of people in the Ham radio community that could use our software.

You missed a step called a directional coupler. It's a sort of
transformer with 2 input ports and 1 output port. The 2 inputs don't
see one another but their power is combined at the output.

A*s*i*m*o*v

IMHO, it would be of benefit if the no-code class, rather than limit one to commercial based equipment, be forced to use homebrew TX or RX equipment.

The only requirement being a power limitation and it meets the spectral purity, etc. regs of the country of origin. Boatanchor or "radio-on-a-PIC", whatever construction.

But you know the government.....

I understand your sentiments. The trend of making rigs very small can also make them more difficult to use. As an example of a rig that is more compact than most commercial off-the-shelf ones, look at the Elecraft range. I love the performance of my K2. However, the front panel size means that each key is often performing at least 2 different functions, sometimes 3. Many on the Elecraft reflector have expressed a desire for a larger FP when more functions could be available by dedicated buttons. So I think that ergonomics comes into play. For even higher component density, again mostly with discrete components, look at the KX1. A fun cw qrp tcvr to build. So it's not always the case that HB rigs have to be very much larger than commercial rigs.

I think much depends on your intended usage. For a base station, as you point out, size doesn't matter that much. I don't think anyone would claim that the IC7800 or FT1000MP was a small rig.
Your suggested size would be fine with me for a base station. For portable, field-day or for mobile or even pedestrian mobile operation, size and current consumption are important attributes, and often some performance and ergonomics are sacrificed in the trade-off for smaller size. Your proposed size would probably be too large for such usage - perhaps, something in the region of a quarter of that volume would be more appropriate.

Another factor is the extent to which you want to remodel the rig after experimentation. I think a

lot of HB tends to end up larger because it was prototyped using construction techniques (such as
ugly bug) that are good for prototyping and changes, but then when the design has iterated to
something near optimal, it is never rebuilt using denser construction such as double-sided PCB.
Perhaps it's a case that the constructor has got their satisfaction with design and are less
motivated by better engineering its construction. I know that some are and like to aim for more
production quality, often taking as much time in that area than the original design and
prototyping. However, I suspect that they are in the minority.

The correct size for homebrew equipment is the following:

1) The size that you feel most comfortable with. Many individuals do not want to duplicate the ultra compact construction methods that electronics corporations use. That is hard and tedious work, for sure, done by people who are experts in that area. Those nifty little boxes that we buy began life spread out and haywired together over a large table top. I have been through that many times.

2) The goal that you have in building your own equipment. Many folks consider their homebrew equipment as "test beds" for future experimentation, refinement and possible redesign. I am one of those, and an example is on QRZ.COM (W0IYH). If you build this gear as a very compact "ship in a bottle" project you are pretty much "locked in" to whatever you come up with. Major modifications become doubly major projects.

3) The average amateur, working in his basement (that's me) has a very lengthy and arduous task to duplicate what a room full of engineers do for a living. Not only that, those folks very often don't redesign everything from scratch, they improve and redesign iteratively over several years, building on what they have done on previous models.

4) Finally, there is a big difference between a) duplicating a published design and b) struggling with your own (and possibly unique) design. In the latter case we need hardware and software that are easily accessible.

The experimenter's code is "Nothing is permanent".

GM Bill, good to hear you up and about. The curmudgeon (Sorry all you curmudgeons for the insult) that started this thread hasn't the common sense or native intelligence to pose the question. He's just there to troll and present his agenda that he is better than others. Obviously the answer is "as big as it needs to be to house the intended materials" and not the other way around. I put the poor soul in my plonk box some time ago and hadn't seen hide nor hair of him in some time until your byline showed up.

I still haven't found my stray resonance in my MRF-150's that causes the gain dip at 32 MHz. Haven't looked real hard for it since it's so eminently flat from 2-30, it's just that it's also useable on 50 MHz and there's just a little 4 dB droop that comes right back up above 35-36 MHz. What with the state of the solar cycle, and with what my age for the next one will be, I suspect I shouldn't be so concerned about it.

I know that with your design philosophy, your 150's are going to last forever, but just in case you ever get a thunderstorm in CR that does you dirt, there's an awfully good buy running around on E-Bay at the moment. ERB Engineering built the solid drivers for the tube amps for MRI machines and a large number of them have turned up on the surplus market. They include a pair of MRF 150's as well as a LOAD of other goodies and usually go for less that the price of a singleton. They don't have the matched pair codes, and with the computer controlled bias the way they set them up they can get away without them, but they DO have the same batch codes on both the ones I bought. Search on MRF-150 amplifier.

Regards

W4ZCB

Hate top posting, you always loose the question.

Since I do experiment and modify I allow for it. I enjoy building
small. Since many of my designs are elaborate I've gotten used to
working in small spaces and laying out circuits for accessability and
considerations for possible future changes.

Sometimes I will work around an existing package. I have a number of
of old computer serial A/B switches. They are aluminum with a rounded
side top and bottom shell. The front and rear plate form a simple
frame to screw the case into one unit. It's a trivial task to make
replacement front and rear as the original have too many holes. I got
these for free when a local merchant decided they were of
insufficient value to store for sale.

My latest project is a 5Wpep SSB tranceiver for 6M band in a package
thats only 2x5x7 inches with PLL tuning and digital display. The pll
module is only 1.5"x1.5"x1" constructed dead bug on pcb material
which also forms the case/shield. It could be made smaller but,
that was adaquately small for this project. The power amp is three
transistors of VHF types and fits in a strip of 1.25"Wx 2.5"L x1.5H
excluding heatsink(case is aluminum). For 10mW in I get 5W pep
with good IMD. The front end (rf amp, mixer and mixer amp) is
complete [1x1x1..25"] and is both compact and very low noise.
The bandpass filter assembly and the crystal filter IF amp sections
are done too. The rest will easily fit in that box obviously.

When doing this I have to consider mechanical things like connectors,
controls and other parts that may be physically large compared to the
circuits they control. For example the froont pannel has to to have
a volume control, RF gain, tuning , microphone jack, headphone jack,
frequency display and meter for RX signal and tx power all in 2x5
inches. The RF gain and volume will have to be a dual (coaxial)
control to fit it all. As you can see getting all the knobs in place
can be more difficult than the electronics behind it.

The only components that will not be in the box will be microphone
dattery and antenna. I exclude the antenna (portable 3 element beam)
and battery power as this is an excusion radio. A 10AH battery of the

gell electrolyte type will be adaquate for a 24 hour field use.

Small is not hard and doesn't contradict high perfomance.

==========

A example of good ergonomics are the Watkins & Johnson commercial receivers , in a 19 inch enclosure with a large functional front panel. Inside a tiny switch mode power supply and a few small PCB modules ; the box being about half empty .

Same with my old TenTec Paragon transceiver ,a large enclosure with ergonomical FP and separate cable linked modules inside.
Also for homebrew equipment using a relatively large enclosure ,you have a large FP and oodles of space to fit separate screened modules which can be individually tested (building block method). The RF modules based on 50Ohms IN and 50Ohms OUT can be readily interconnected with ready made short coax leads with SMA or similar connectors . These links can be found at flea markets , probably surplus leftovers from the mobile phone industry.

>"radio-on-a-PIC", whatever construction.

That exists already/

Here in the USA:

Tech limited to bands starting at 6M (50mhz) and up to whatever.
Power is 1500 max, any mode, build, modify or buy. No CW required.
All modes permitted unless restricted by band use, SSB, FM, Fastscan
TV, Data/digital, and even CW. Even if you have not taken the CW test
and you think you can do it you can use it.

Tech+ same as above with code, limited access to some of the HF
bands.

General same as Tech(all permitted modes per band), required 5wpm
code and grants access to the MW and HF bands (160 thru 10).

Extra all of general privledges plus acces to some of the subbands.

I happen to like that mode. Also testing with a 50ohm path is easier
and can make it possible to build simple test fixtures on the bench.
I build modues usually using PCB material soldered up and test each
stand alone. The beauty is you can optimize that function and if at a
later date you wich to try different it can easily be remove and a new
design substituted. Also shielding is inherent, that alone in many
cases is a performance improver. Testing is easy on the bench
as nothing has to be mounted to work and once satisfied you transfer
the modules to a practical package. Repair show somethign fail is
simplified as you can remove the offending module and fix or outright
replace it by building another, and maybe improving it.

I'd take a look and a grounding issue. Last I played with MRF150s I
forgot to ground the top to the bottom side of the board right where
the leads intersect (the hole wher ethe MRFs meet the heat sink).
A peice of .003 copper shim stock from the top to bottom at the hole
fixed it along with a few places in the board (#18 wires from top
ground to bottom ground) seemed to clean it up. Then I first
encountered the problem I thought it to be a device lead length
problem on the input or output. HIgh RF current at low imedences
can really show things you'd never notice at lower power.

I have a Royal Canadian AF Xmitter, P/N BC-458-A, that I picked up in my town's recycling center. It has a sticker on it that says it was certified operational in 1953. The frequency range is 5.3 to 7 MHz. Missing are two VT136 tubes. Otherwise it appears to be as prestine as a greater than 50yr old elecyronics gadget can be. It contains two tubes, VT 137 and VT138, as well as a tube shaped 7000KC xtal.

If you want it, I will sent it to you for the price of the shipping and for whatever extra you think its worth to you. It hefts at about 5lbs. (?)

Reply to this newsgroup if interested.

> today's ham's rarely fit the bill :-(

> What happened?

Way Back When I Got Started, in 1962, the difference between what I could build at home and what I could buy from a manufacturer wasn't all that great. The high-end stuff got fairly fancy, as indicated by the Collins A-line gear, but mostly it was fairly mundane.

But that was when commercial transistor gear was moderately new and much (or most) commercial stuff was tube-based. There were _no_ ICs, definitely no computer-controlled rigs, and Life Was Much Simpler. The overall performance level of rigs was lower, as a result.

Nowadays the commercial gear is *SO* much more advanced than anything the average ham can design and build[1], or even build from a design someone else worked out, that it's just easier to buy an appliance to get the performance one wants. Construction is hard, it requires time and expensive materials, and the overall bill for the appliance most of the time is less than it would cost (including time) to build a comparable device.

[1] There are exceptions, and they appear as showcase examples in the ARRL Handbook and other places.

Just because plenty of people are willing to give away software for free (which is great and should certainly be encouraged) doesn't imply that 'pay' software can't be useful and well worth the money. There are many examples of software out there where the free stuff still doesn't come close to containing the functionality of the pay versions... although of course there are also plenty of examples where the free stuff is as good or better than the pay stuff!

shrug It is certainly a handy thing to be able to do. With all the
amateur radio software available to Win32 users, it makes sense for many
to run Windows. Having the option of running X apps from a headless
server just adds more value to both systems, and is a great way to
extend the usefulness of your network.

The only problem I've run into is that these are X emulators. This
means some apps will behave strangely, or not work at all, when run in
this environment. Java Swing/AWT apps are notorious for this
(InstallAnywhere, I'm looking in your direction.)

*nix-based operating systems like Linux, *BSD and Mac OS X can benefit
from running a local X server, with the added benefit that these are
"real" X servers, allowing problematic Java apps to run.

Long time no speak! Sorry I didn't make it to the rally last week, I would have liked to meet you.

You know, if we got to see some of the interesting homebrew kit and modifications that you frequently talk about, I am sure that it would stall many of the "outbursts" that you attract and refer to. If you don't have access to a camera or scanner, written desciptions would be fine. I am sure that that your designs would be both an inspiration and a help to many of us who would like to have the benefit of your knowledge and experience.

If you don't have a website, you can either email or post me your designs and I'll be glad to publish them for you, of course giving you full credit, as I have done for a few others' designs that I've published on the authors' behalf.

My email address is on my website and my address is in qrz.com and the Yearbook back to 2001.

Thanks & 73, Howard G6LVB

There's no universal way to do this, since PC sound cards don't have consistent output levels. Full-scale-digital output signals are often at 1- or 2-volts peak-to-peak on the line-level output jacks, but they're often at different levels depending on the PC's sound chip, amplifiers, whether there's a headphone amp involved, etc.

In one case I encountered (my Dell Latitude CPxj) turning the PCM-out control all the way up to full scale resulted in horrible digital clipping of the signal, *before* the sound interface's master volume control. I had to turn the PCM output level down to about 30% to get a clean sinewave output.

The best I can suggest is that you generate the tone that you need using the PC software you have, feed the line- or headphone-level output from the PC sound card to an analog volume control (a 1k or 10k audio-taper pot is probably a good choice), and use a reasonably well calibrated oscilloscope or DVM to measure the resulting voltage and trim it to 3 millivolts (P-P or RMS, depending on what the calibration procedure asks for).

I'd recommend using a 'scope, to confirm that you're actually getting a clean signal.

It's best to measure the actual signal level "in circuit", with the PC/generator and the attenuator driving the rig's transmitter. If you measure first and then attach to the rig, the rig's input impedance may shift the level enough to perturb your calibration procedure.

Point taken. Myself, I am a tubehead, but I would love to design a
PLL-PIC based VFO for my tubes. After all the readin' and studyin' I did
on the subject, I have come to the conclusion to let a dedicated
solid-state-aholic mate design one and I just build it.

Are we just too old?

Yeah, I know about that except I don't have another Linux box to use.

>
> I can see no advantage to running an exported xsession from a *nix machine
> to a windows desktop.

Except when that is all you have access to use. I have a company laptop,
which I can't install Linux on, and is setup for Win 2K so I don't have much
choice. I'm limited in what I can carry out in the field so I don't have the
option to get another laptop, which the company won't install their software
on for me to use. And I'm not lugging around two laptops. Same goes for my
office desktop computer too, only company approved major software apps,
small utilities they don't mind so much.

In general that is what Micro$oft is hoping to have happen, if not already.
Then Micro$oft will begin moving to a "subscription" based licensing model.
They will have to do this when the market reaches saturation and new
software sales begin dropping. They will then use the new subscription based
licensing model to keep their revenue stream going if not increase it. At
that time GPL based software will be much more appealing.

Once again, you're misreading the rules.

As I told you last summer, whether someone has passed the code test
or not has no relevance. It's whether someone has passed the advanced test.
Since it's a mix and match system, people can pass the advanced test
without taking a code test. They can build all the transmitters all

they want at that point, but since they haven't passed the code test
they have no HF privileges.

There is no "no code license" in Canada. There are two levels of license,
and either one can be no-code.

You don't actually *need* a directional coupler. I have seen window preselectors with five separate sections for sub-bands between 403 and 520 MHz. The configuration is symmetrical (in/out) with simple bandpass filter segments and coaxial split/combine harnesses. Not a DC or hybrid in sight. I am presuming - not having swept one - that at "off" frequencies each parallelled leg presents a high enough impedance to the split junction that the effect is negligible.

Well, there is a lot more than that. Most of us interact from time to time
with other people, and it's a Windoze/Office world out there. Sorry, that's
the way it is. You can wish all you want, and you can prattle on about how
much better open source stuff is, but the real world is Windoze/Office.
Most of us don't have the luxury of hiding in our hole and pretending that
the outside world doesn't exist.

Even if we can afford/control another box, most of us also have physical
space limitations. I only have room for just so many keyboards on my desk,
and it is a major pain in the butt to have to walk around to another desk to
get to the Linux console. (Yeah, I probably have more space than most).

I run X sessions from Cygwin on a couple of Windoze machines, and it works
quite well. Earlier in the thread there was a mention about windows
behaving weird under Windows, but I haven't seen that. Indeed, if the X
implementation is anywhere close to correct, you shouldn't see that.

But it is a huge convenience to have both the Linux *and* Windoze tools at
my fingertips.

Yes but it requires some effort and cost to build the 2nd BP filters so
I wonder if it's any more difficult to do either? What do you figure?

If cygwin doesn't cut it, there is an application called vmware that lets you create virtual machines on a single box.

I've seen one instance where an application running on a virtual machine with win2k installed (physical machine was linux) actually ran faster on the virtual machine than it did with win2k installed on the physical machine. Doesn't make much sense, but there ya go.

virtual machines let you experiment with all kinds of OS stuff without trashing a "production" machine. I've had virtual machines with win2k, redhat 7.3, redhat 9, solaris x86 all on one box without shutting down the native OS (which happened to be mac OS).

The biggest difference between virtual machines and dual boot is that you can have 'em both running at the same time.

Elecraft has several kits that build an advaned transceivers with
microprocessors and digial pannels. The average hams do build them
and when done can even fix them.

>Point taken. Myself, I am a tubehead, but I would love to design a

There is an outfit that has kits to do exactly that. Also there
was/is the Amqrp [http://www.amqrp.org/] DDS VFO daughter board.
That with the PIC-el kit was a quick means for me to bootstrap into
using PICs and DDS for my Rf perojects. In the past I've used micros
but ahving the tools and a a really nice course on a specific one was
a useful assist.

I wasn't sure if the countries involved but my understanding was
Canadian rules are similar to US in style and form. Other countries
are beyond my knowledge. I'd expect from articles I've read
and the calibar of those authors there are many that allow home built
equipment and may even encourage it.

I'm not so sure I'd call someone building an Elecraft an 'average ham.'
Especially with the K2, there are enough parts in there that most people who
build it are probably already seasoned kit builders. Indeed, there are even
lists of hams out there who will assemble Elecrafts for other hams who
don't have the skills or desire to put the things together!

Still, I think there are plenty of homebrewing opportunities available to
hams (the ARRL's publication of "Experimental Methods in RF Design" last
year bolsters this argument), just that a smaller percentage of hams than in
prior years chose to avail themselves of the option.

There will always be folks out there experimenting with radio -- look at how
popular WiFi 'hacking' is and even low power FM!

When things were restructured here back in 1990, the basic test/license
specifically forbade the use of homebuilt transmitters. It's only
after one passes the advanced test that one can use homebuilt transmitters
(and it allows for 1000watts input versus 250W for the basic license,
and the control of repeaters).

But his error is in reading the rules to mean that you have to have code
to pass the advanced test, and thus to build transmitters. The code tests
(back then there were both a 5 and 12wpm tests, now it's only 5wpm) were
independent of the written tests. With no code test, but the advanced
license, one has full privileges, though it all has to be above 30MHz.
The code test(s) only add HF capability, whether you have the basic
or advanced license.

This is in contrast to the US model, where advancing did require a code
test at some point.

Up till 1990, of course anyone with a ham license here could build their
own transmitter (and the only thing the advanced license gave was
voice on HF). When I was licensed back in 1972, it was still called
the Amateur Experimental Service, though that full name was dropped
at some point without comment.

The impression people had was that since few were building things,
then this wouldn't affect many. But by making the written test
simpler, it would "make it easier" for people to enter the hobby.
I've not realy looked over what the test is like, but I sure had no
problem passing the test back in 1972, when I was twelve. But ironically,
if few are building things, those few won't be doing much damage even
if they don't know what they are doing. Indeed, it's likely that only
people who know what they are doing would be building, hence the state
of the test shouldn't matter.

I don't like the rule, since it does change the hobby, and institutionalizes
a perception of the hobby.

But like I said, code has nothing to do with whether or not someone can
build their transmitter.

I'm not sure we are on the same wavelength here (no pun intended). For
non-overlapping filter sections, the bandsplit through two bandpass sections
25-500 and say 550-3000 should be able to be achieved with T-pieces at the input
and output ends (although it appears the O/P didn't achieve this).

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----ooooo----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing

of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

Your troll bait is becoming boring. However, for the sake of any
newcomers who might be misled it, a slight amount of correction
needed.

Although it is unclear what a 'radio ham' is, it should be noted that
anyone canspecify, design, construct, align, test, modify, adjust,
and even own such radios without a licence.

The only licence needed is to cover 'installation' and 'operation'.

Amazing how that latter term, which you used to use as a term of
derision, has disappeared from your Gospel.

Try googling with "polyphase quadrature network"
I have used one of these as an RF network which worked acceptably well
to 30 MHz, though losses were significant.
I seem to recall the original article described one of these, though I
am not sure.

We have a mix of Linux, Windows, Solaris, etc machines at my home
and office. When it comes to outstanding convenience and price (free!)
nothing beats VNC. Much, much faster than X, multi-platform, and you
can even issue a 3-finger-salute to a remote Windows box,
when necessary. Heck, I've controlled both Windows and Unix boxes
with it from my Palm, when I was too lazy to walk to over to my laptop. ;-)

Particularly when you run the Xvnc server on a Linux box, the
interface is all-but-indistinguishable from running X locally, no matter
what machine you're actually sitting at.

Airy R Bean - may I offer the following text document as guidance prior to tackling writing a FAQ:

Archive-name: faqs/about-faqs
Posting-Frequency: monthly
Last-modified: Aug. 8, 1995

This article is a description and primer on Frequently Asked Questions (FAQs) articles and lists.

The following topics are addressed:

1) WHAT ARE FAQs?
1.1) What does FAQ stand for?
1.2) How is FAQ pronounced?
1.3) What do FAQs contain?
1.4) What are FAQs used for?
1.5) Where are FAQs found/kept/hidden?
1.6) What was the first FAQ?

2) WRITING A FAQ
2.1) Who may write/compile a FAQ?
2.2) Why write a FAQ?
2.3) What subjects are appropriate?
2.4) How important is accuracy?
2.5) What is the format for a FAQ?
2.6) What is the maximum size of a FAQ?
2.7) What is a header and do I need one?
2.8) Additional information

3) POSTING A FAQ
3.1) How do I post/distribute my FAQ?
3.2) Where do I post/distribute my FAQ?
3.3) How often should my FAQ be posted?

4) LEGAL STUFF
4.1) Do I need to copyright my FAQ?
4.2) Do I need a disclaimer?

5) APPROVAL FOR *.ANSWERS - THE BIG TIME
5.1) Why bother getting a FAQ approved for *.answers?
5.2) How do I get my FAQ approved?
5.3) FAQ maintainers
5.4) FAQ maintainers mailing list

6) ACKNOWLEDGMENTS

1) WHAT ARE FAQs?

1.1) What does FAQ stand for?

FAQ is an acronym for Frequently Asked Questions. It is also sometimes used as the singular Frequently Asked Question (Although when was the last time you heard only one question?).

Some have called it Frequently Answered Questions as well. This isn't necessarily correct, but it isn't necessarily wrong either. It effectively has the same meaning.

A compilation of Frequently Asked Questions (and their answers) is referred to as a FAQ list or FAQ article. Sometimes the term FAQ itself is used to refer to the article - as an example, I refer to this article as a FAQ about FAQs.

The term FAQ has a meaning of its own that could almost qualify it as a word of its own. Sometimes, FAQs are full of answers. Other times they are policy statements for USENET groups, without the Question and Answer format that is popular.

FAQs fall into the realm of articles called "Periodic Postings". In addition to FAQs, other articles or compilations of information are posted and/or archived.

1.2) How is FAQ pronounced?

FAQ is pronounced three ways:
1. By pronouncing the letters individually: F - A - Q
2. As a word: fack
3. Obscenely:

The first two pronunciations are the most common, and are used about equally. Some will say F - A - Q if they are speaking with someone that really doesn't know the Internet. Those who are lazy (me for example) will use "fack", since it is easier to say. Often when initiating a conversation it is useful to say F - A - Q, and then once the subject has been established, "fack" should be sufficient.

You will notice that in this document I use the phrase "a FAQ" rather than "an FAQ". This is because most of the time I say "a fack" instead of "an F-A-Q".

Feel free to use whichever pronunciation you prefer and don't let anyone bully you. Both ways are acceptable. If you use the third way... well, you're on your own.

1.3) What do FAQs contain?

FAQs are compilations of information which are [usually] the result of certain questions constantly being asked (posted) in a newsgroup - hence the name FAQ (Frequently Asked Questions).

It seems that those who frequent USENET are a polite bunch. In my house, the "frequently asked questions" that my three rug rats come

up with are usually referred to as stupid questions or pestering. There is a lesson to be learned from this... before asking a question in a newsgroup or mailing list, make sure that you've checked out the appropriate FAQs. A frequently asked question can be a stupid question if the answer is posted right in front of your face in one or more FAQs.

Sometimes a FAQ or periodic posting is compiled as a result of extensive research on a specific subject. A convenient way to share the information with others is by posting the article. In this case, the article might not really be a FAQ - that is, it isn't necessarily based on frequently asked questions. However, the term FAQ is sometimes used as a catch all term for articles, periodic postings, compilations, etc.

It is becoming common practice to refer to some "off-line documentation" as FAQs. Yes, it's true, off-line documentation still exists, I actually saw some a little while back ;-). All sorts of stuff now comes with support-staff-written FAQs, whereas they would have been called Q&A sections before.

Many of the FAQs found on USENET or the Internet today (including mine :-) could actually be considered NSFAQBTIWTS - Not So Frequently Asked Questions, But Things I Wanted To Share (thanks to Robin Getz for this gem). I've also seen them referred to as LFAQ (Less Frequently Asked Questions). Is there no end?! Where is Chicken Man, now that we need him?

1.4) What are FAQs used for?

Before asking a question in a USENET newsgroup, check out the appropriate FAQs. If you can't find the answer to your question there, then you can post your question to the newsgroup. Frequently asked questions in a newsgroup tend to make the news hard to read. With more news traffic, there is more to sift through. Do everyone a favor, first try to find the applicable FAQs. Then read them. If you can't find them, look for them. If you still can't find them, ask where they are. Then read them.

If after reading the appropriate FAQs, you still can't find the answer to your question, then you can post your question to the appropriate newsgroup. It is recommended that after you receive your answer(s), you post a summary to the newsgroup. It might also be nice to notify the maintainer of the appropriate FAQ(s) of the answers so that they can update their articles accordingly (keep in mind that they don't always have the time to scan the newsgroups for new information).

Don't assume that the FAQ maintainer is willing or able to answer every question he or she receives. Some make every attempt possible to answer as best as they can. Others either just get too many questions to deal with, or they're busy with other things. Please

keep this in mind - it might be better to ask your question in a newsgroup.

1.5) Where are FAQs found/kept/hidden?

Please do not ask the FAQ maintainer to mail you a copy of their FAQ. They just don't have the time - believe me, I know. Instead, make every possible effort to obtain the FAQ from the standard locations described in this section (USENET newsgroups, archives, etc).

1.5.1) USENET

FAQs can be found all over the Internet. The most common place to find FAQs are in USENET newsgroups. USENET is a distributed discussion system that exists on the Internet and some other networks. Many newsgroups have a FAQ specific to the subject of the newsgroup. It is also common, in some newsgroups (that by nature cover more ground), to have a number of FAQs on different, pertinent subjects. Some FAQs that have been approved by the *.answers moderators team (more on this in section 3) appear in the various *.answers newsgroups (news.answers, comp.answers, sci.answers, etc). A quick browse through these newsgroups will turn up many interesting articles - do yourself a favor and check from time to time.

1.5.2) Mailing lists

Many mailing lists also have their own FAQs. Some mailing lists automatically mail the FAQ to the list of subscribers. Other lists send a notice advising subscribers how to get a copy. The second option seems to be the most prevalent. An important reason for this is that most FAQs are fairly large (some are even multi-part), and it wouldn't make sense to periodically mail it out to an entire mailing list. Some mailing lists automatically mail the FAQ(s) out to new subscribers (probably with the hope that this will avoid stupid questions), and then letting the subscriber retrieve updated versions of the FAQ(s) by ftp.

1.5.3) Archives

Many FAQs are also archived. One important repository of FAQs and other articles is the news.answers archive maintained by the moderators of the news.answers newsgroup. All FAQs that have been approved for posting to the news.answers newsgroup are archived at the rtfm.mit.edu ftp site (and all of the mirror sites) in the following directories:

By subject line -
/pub/usenet/news.group.name
/pub/usenet-by-group/news.group.name

By subject category -
/pub/usenet/news.answers
/pub/usenet-by-group/news.answers

and for the other *.answers newsgroups
/pub/usenet/*.answers (eg. comp.answers, sci.answers, rec.answers)
/pub/usenet-by-group/*.answers

By newsgroup hierarchy -
/pub/usenet-by-hierarchy/news/group/name

To find a FAQ by the newsgroup it belongs to, look in the directory /pub/usenet (which is the same as /pub/usenet-by-group). There you will find that each newsgroup has its own subdirectory (if applicable). As an example, if you are looking for one of my FAQs on microcontrollers, look in /pub/usenet-by-group/comp.answers/microcontroller-faq. There you will find three entries: 8051, 68ch11, and primer.

You can also search for FAQs by working your way through the newsgroup hierarchy. Look in the directory /pub/usenet-by-hierarchy and you will find a subdirectory for each newsgroup category (news, comp, rec, alt, ...). Then just keep working your way down the hierarchy by entering the appropriate subdirectory to find the FAQs that you are looking for. For example, to find my FAQs on microcontrollers, look in /pub/usenet-by-hierarchy. Go into the comp subdirectory, and then go into the answers subdirectory. All of the FAQs posted to comp.answers will be listed under this directory.

Instead of searching through the archive, many of the periodical postings on USENET are listed in the news.lists newsgroup under the heading:
"List of Periodic Informational Postings, Part * *"
These lists are archived at /pub/usenet/news.lists with the archive names:
"List_of_Periodic_Informational_Postings,_Part_*_*"

If you do not have access to anonymous ftp, you can also send e-mail to mail-server@rtfm.mit.edu to get FAQs by e-mail.

Initially, try a message with no Subject: and just the following lines in the body:
help
end

One useful command is the index command. This returns a list of the contents of a particular directory. Some examples of how to use this command are:
index
index usenet-by-group
index usenet-by-group/news.announce.newusers
index usenet-by-group/news.answers
Be warned that news.answers has a LOT of information in it. The directory listing that will be sent to you by Email will be LARGE.

1.5.4) World Wide Web

If your system has a browser for the World Wide Web, then you can access all of the USENET FAQs found in news.answers (and lots of other good stuff!) at these addresses:
http://www.faqs.org/faqs/FAQ-List.html
http://www.cs.ruu.nl/cgi-bin/faqwais
http://www.lib.ox.ac.uk/internet/news/faq/by_group.index.html
[non-functional now]

The World Wide Web uses hypertext links, contained in HTML (HyperText Markup Language) documents, to join pieces of information located either at the same or different sites. The links are in the form of URLs (uniform resource locators), a standard way of coding the location of hypertext information.

Check with your system administrator or on-line service for more information on how to access the World Wide Web.

1.5.5) Collections and Compilations on CD-ROM

This is a controversial subject among FAQ maintainers. Even my mentioning this subject puts me in danger ;-). Many FAQ maintainers (such as myself) object to the practice of some firms grabbing everything available from the USENET archives (including many copyrighted FAQs), putting it on a CD-ROM, and then selling it.

In some ways, the idea of a FAQ being distributed in a CD-ROM collection isn't necessarily evil. After all, the main idea behind writing the FAQ in the first place is to share information with others. The CD-ROM is another way to share this information. It even gives access to those who don't have access to the Internet.

On the other side of the coin, you'll find many FAQ maintainers who think that the whole idea of restricting the distribution of FAQs (theirs in particular) is misguided. That's fine - the owner of a FAQ can set whatever conditions for distribution that they want.

The basic objection to the use of FAQs without the permission of the author, is one of control over copyrighted material. The FAQ maintainer works hard at compiling and maintaining the FAQ. The issue is not one of greed, since it is clear that the FAQ maintainer wants to share with others. It just isn't fair for someone else to make a buck at it.

Some FAQ maintainers are fussy about the most recent information being available. A FAQ on a CD-ROM is out of date - PERIOD. The only place to get a FAQ, and be sure that it is up-to-date, is from the appropriate USENET group (or archive). It should be the right of the FAQ maintainer to decide what to do with the FAQ.

Finally, the practice of using copyrighted works without permission is illegal. Most FAQ maintainers have a copyright statement, along with the phrase "all rights reserved", appended to their FAQ. Therefore, the FAQ maintainer, and no one else, has the right to do whatever (s)he wishes to do with the FAQ.

If you come across such a FAQ (with the appropriate copyright statements) in a commercial collection, please notify the company you purchased it from that what they are doing is illegal. It would also be appropriate and appreciated if you would notify the author of the FAQ that his/her FAQ is illegally being sold.

Many popular magazines have advertisements for collections on CD-ROM of Internet/USENET archives. I cannot verify whether they adhere to the proper legal practices in the compilation and distribution of the contents of their collections. I'm not even sure if I (personally) agree or disagree with the practice. Please keep the FAQ maintainers' interests (and feelings) in mind.

1.6) What was the first FAQ?

Eugene Miya is usually credited with being the author of the first FAQ. Although, in his words, "I didn't do the very first FAQ, but I probably did the first one of an informational nature." His article might possibly be the first one that was called a FAQ. Eugene points out that Mark Horton kept an "18 question" periodic post. This was posted to "general", which was later called news.announce.*. It had answers to questions such as "What does 'foobar' mean?" and "What does 'unix' stand for?"

In 1982, while acting as an official NASA presence on the gatewayed ARPAnet mailing list SPACE[-Digest]/net.space news groups, he tired of seeing "dumb answers" to recurring questions. The situation as Eugene saw it was that the answers to these questions were are often poorly thought out, inconsistent, and uninformed. Furthermore, the posters of the questions often weren't trying to find the answers from books, magazines, or other references. They also weren't paying attention to previous answers to these same questions. Rather, they were just taking the easy way out - email the question and wait for the answer.

Eugene therefore decided to start a series of monthly posts in 1983 to rectify this sorry state of affairs. The mechanism of periodic postings was also a way to provide information to those who didn't have access to the archives.

The first posts included the addresses of NASA Centers, some basic references, etc. He also had a yearly posting trying to attract summer hires for the various NASA centers. All of these are still being posted, albeit by someone else now.

2) WRITING A FAQ

2.1) Who may write/compile a FAQ?

Anyone - no rule exists about who may or may not compile/write a FAQ. If there is a need for the information contained, your FAQ will be appreciated.

2.2) Why write a FAQ?

The Internet (and USENET) is frequently referred to as the Information SuperHighway. You can argue the merits of this analogy, but you can't deny that there's lots of stuff out there. The big problem is finding it - and I mean BIG PROBLEM. It might be more accurate to refer to the Internet as "the large, multi-storied, over-crowded, Information Parking Lot." And the attendant is away!

One thing that I've discovered in the short time that I've been on the Internet, is the willingness of those who frequent USENET to help others find their way around this great big wonderful mess. A FAQ is a good way to help lots of good folks at the same time. The first FAQ that I wrote was as a result of my search for information on Intel 8051 microcontrollers. I couldn't find anything for a long time. I used Archie, Gopher, and lots of other methods that I either read about or that friends recommended. In addition, I scanned the appropriate newsgroups. However, all that I could find were the same questions that I was asking. I nearly came to the conclusion that the Internet was a waste of time.

After compiling a few facts, I put them together in a small article (under 5K) and posted it to a few USENET newsgroups that seemed to have a reasonable connection to the subject matter. In a short time I was inundated with Email. Readers of my FAQ from all over the world sent additions and corrections for the FAQ, requests to post to other newsgroups, kind words of appreciation, offers of free software and literature, and even a job offer. Today the FAQ is over 100K in size and two other FAQs were born from the leftovers from this first FAQ.

As a result of this modest effort, I have learned a lot. I have more than enough information about the 8051 microcontroller, I learned my way around the Internet, and I have made connections with a number of really nice people. Even more, my FAQ had a snowballing affect. Several other people are now either maintaining or starting FAQs on other microcontrollers. In a short time, if a newcomer to the Internet is looking for information on microcontrollers, a pile of information will be immediately available, without the need for months of searching. Hopefully, the same will be true about the subject(s) that you are interested in.

2.3) What subjects are appropriate?

Just about anything. If you see the same questions always popping up in your favorite newsgroups, a FAQ might be needed. Check first if a FAQ exists, by looking in the USENET archives and by asking in the newsgroup is such a FAQ exists. If there is no FAQ, and you know the answers (or at least a good number of them), do yourself and everyone else a favor. Compile the questions and answers together in an article, and post it regularly to the newsgroup.

Just as important, make sure that your FAQ is made available to the right audience. This means carefully choosing which newsgroups to post it to. Often, requests from other newsgroups will inform you

that others are also interested in your FAQ.

2.4) How important is accuracy?

If you are maintaining a listing of all of the Gilligan's Island episodes (yeah, there is such a FAQ, and it's great!), the chances of causing serious damage to someone are pretty slim.

However, as a purely hypothetical example:
- if you are maintaining a FAQ on the Pentium processor
- you claim that the Pentium is 100% accurate and bug-free
- someone reads your FAQ, bases a project on this information, and encounters a bug that has terrible consequences
- at the least, you will be considered vermin by your dear reader
- at the worst, you might find yourself being sued by same

Some FAQs are in the business of sharing information about different products. This can be a bit touchy when trying to convey quality or usability. Care should be taken when relying on opinions (even, or especially, your own) or hearsay. Try to check out the details the best that you can. You might consider stating if an item is opinion or fact (whatever that is). Be open for suggestions. The inclusion of a disclaimer might be called for, although it really shouldn't be necessary (see section 4.2).

2.5) What is the required format and style for a FAQ?

No format is required. You are free to be as creative as you wish. Keep in mind however, that the FAQ should be readable. Don't just cobble together a document that has no organization or flow.

One common practice is to organize the FAQ as questions and answers, much like this article itself. This fits in well with the name Frequently Asked/Answered Questions. In other cases, it may make more sense to organize your FAQ as a reference. That is, lots of answers without the questions being stated (asked) specifically. Some FAQs can use both of these techniques in the same document. One part of the article can be in question/answer format, while the rest can be a reference.

It is highly recommended that you establish a consistent and easy to read format. For this document I chose to use a hierarchical numbering system, but you may prefer another method (e.g. Roman numeral, Capital letter, number, small letter). Indenting the text also makes it easier to read the document (Ask just about any graphics artist, and they will tell you that white space is important). If you prefer a particular formatting technique, by all means use it. Just please keep in mind that everyone will get more out of your efforts if the result can be easily read.

In addition, a FAQ can be in straight ASCII, or in several other special formats. I prefer using straight ASCII since it is more easily accessible to a larger number of users.

One proposed format is "FAQs: A Suggested Minimal Digest Format".
This article is posted periodically to:
news.admin.misc, news.software.readers, news.answers
The author is:
clewis@ferret.ocunix.on.ca (Chris Lewis)
This article is also archived as:
faqs/minimal-digest-format

Another format is the html document standard for use on the World Wide Web (WWW). This is becoming a popular way to "publish" information, however there are some disadvantages:
- HTML is NOT an easy-to-understand language
- not everyone has access to the Web

It is becoming common practice to maintain two versions of a FAQ. One is in straight ASCII and is posted to the appropriate USENET newsgroups. The other version is in html and is made available on a web site, giving the reader easy and instant access to the various site links contained in the FAQ.

Grammar and spelling are also important. Poor grammar can cause ambiguities and make it difficult for the reader to understand what you're trying to say. Spelling mistakes are distracting, and can also create confusion. Although it isn't necessary to work towards a doctorate in English literature, take a few moments to review your work and clean it up.

2.6) What is the maximum size of a FAQ?

FAQs have no size limit, although sometimes a system may impose certain restrictions - 64K is always a magic number. I've also seen 100K used as a limit. In addition to system limits, FAQs that are very large (over 64K) might be difficult to handle. You might consider splitting your FAQ up into pieces, with each piece having its own theme.

Many old USENET sites will not accept articles over 64k. Some on-line services have smaller limits (32k for America Online). FAQ maintainers have to make a trade-off between the universality that they wish their FAQ to achieve, and the convenience of one large article as opposed to several smaller articles.

The trend seems to be towards keeping FAQs in one piece, no matter how large they get. I recently asked the readers of my microcontroller FAQs if they wanted the FAQs split into multiple parts or kept in one piece. Even though two of the FAQs are over 100K, and the third is approaching 100K, the results were unanimously for keeping each of the FAQs intact and in one piece. The convenience of not having to juggle different pieces of the document (both for the author/maintainer and for the reader) outweighs the inconvenience of an occasional newsreader program that can't handle large articles. Also, most on-line services are in the process of removing size restrictions, making the size of the FAQ more dependent

on personal taste, and less on "technology" (or the lack thereof).

2.7) What is a header and do I need one?

A header contains descriptive information about your posting. If you post your FAQ by means of a newsreader, a [minimal] header will be supplied automatically. This header is required by the posting mechanism.

Providing additional header information isn't really crucial unless there is a specific need (such as providing a version number). If you are considering submitting your FAQ for *.answers approval, certain header information is required. See section 5 for more details about this. If you aren't worried about approval for now, then you don't need to worry about the header either.

2.8) Additional information

There are several additional sources of information on FAQs and FAQ writing.

David Alex Lamb's "FAQ maintenance aids":
http://www.qucis.queensu.ca/FAQs/FAQaid/

Infinite Ink's (Nancy McGough) "Finding and Writing FAQs and Periodic Postings":
Finding FAQs:
primary - www.ii.com/internet/faqs/
mirror - http://ii.best.vwh.net/internet/faqs.html

Writing FAQs:
primary - www.ii.com/internet/faqs/writing/
mirror - www.best.com/~ii/internet/faqs/writing/

The bible for getting your FAQ approved by the news.answers team is the *.answers guideline. This document has been recently revised by Pamela Greene (one of the news.answers moderators) and is posted monthly to news.answers. See section 5.2 for more information on getting this document and having your FAQ approved.

Eugene Miya has an article "FAQ on FAQs n.g.FAQ" posted to:
news.groups (hint: the n.g. is short for news.groups).

3) POSTING/DISTRIBUTING A FAQ

3) POSTING A FAQ
3.1) How do I post/distribute my FAQ?
3.2) Where do I post/distribute my FAQ?

6) ACKNOWLEDGMENTS

3) POSTING/DISTRIBUTING A FAQ

3.1) How do I post/distribute my FAQ?

If you only need to post your FAQ to one or two USENET newsgroups (or mailing lists), then you can just manually post it whenever the posting date rolls around. It is also possible to cross post it to several groups at once. Check with your system administrator for more details on how to do this.

Some sites don't keep their news around for a long time, so your posting might disappear from those location sooner than you planned. For this reason, and to allow general access to your FAQ, it is a good idea to archive it somewhere if possible. This might be on a friendly ftp site that agrees to keep the current copy available for ftp'ing, on a mail server, or on your own system (as long as others have some sort of access).

If your FAQ is to be posted to a large number of newsgroups, then it might be a good idea to take advantage of the faq-server set up by the *.answers team. The faq-server can be used to automatically post any periodic posting that is first approved by the *.answers team. It allows automatic posting at set intervals to as many newsgroups as required. A big advantage of using the faq-server is that it is quick, easy, and automatic. Check with the *.answers team for more details on this.

3.2) Where do I post/distribute my FAQ?

Among the many places that you might choose to post or distribute your FAQ:
- USENET newsgroups
- Commercial on-line services (Compuserve, America On Line, BIX, Prodigy, etc)
- Bulletin Board Systems (BBS)
- manufacturers' literature (I have given my permission to several major corporations to include portions of my microcontroller FAQs in various product/technical documents.)
- published works (many authors or publishers like to include portions of the appropriate FAQs in their works, this gives the reader an easy way to find more information on the subject)
- a number of FAQs (as well as other articles that started out as information guides on USENET) are now being made available in print (these range from full-blown works issued by major publishers, to simple pamphlets printed privately)

3.3) How often do I post/distribute my FAQ?

Posting your FAQ once a month should be sufficient. In some special circumstances, you might need to post your FAQ twice a month to keep it available in the newsgroup. Adding an expiration date in the header also helps keep it from being purged too soon. This doesn't always work, since your local system determines when the articles will be purged, and this doesn't always coincide with the expiration date.

4) LEGAL STUFF

4.1) Do I need to copyright my FAQ?

If you invest a lot of time on your FAQ, and most FAQ maintainers do, you might be concerned about protecting your work. Under the Berne Convention (to which the vast majority of "Western" nations are signatories), as soon as something is published, then the writer/producer of the item is held to own the copyright. You can add (C) copyright 1995 if you want, but it is no longer necessary (sort of like chicken soup, doesn't necessarily help, but it couldn't hurt).

Protecting your work with a copyright protects your rights if someone else decides to steal your work and make a buck from it. As mentioned above in section 1.5.5, it is very common for companies to compile information from the Internet, put it on a CD-ROM, and sell it. While copyright protection won't prevent this from happening, it at least makes it illegal and gives you legal recourse if you need.

Check the copyright FAQ for further details. If it is important enough, you should consult with a lawyer experienced in copyright law.

4.2) Do I need a disclaimer?

In this "sue the pants off of anyone that looks at me cross-eyed" world that we live in today, many FAQ maintainers are using disclaimers to protect against possible law suits. If your FAQ contains information that might be used in sensitive applications, and if something were to go terribly (and tragically) wrong, do you think that you would be sued? Does a bear defecate in the woods? See section 2.4 (How important is accuracy?) for more information on this subject.

I'm not a lawyer, so I won't attempt to give definitive advice here (yes, this is a disclaimer), but something such as the following might help cover your tush. Whether it in fact really helps or not, I don't know.

This article is provided as is without any express or implied warranties. While every effort has been taken to ensure the accuracy of the information contained in this article, the author/maintainer/contributors assume(s) no

responsibility for errors or omissions, or for damages resulting from the use of the information contained herein.

Another common disclaimer (that you have more than likely already encountered), is that used to disclaim any connection between the author's opinions and those of their employer. If your article is in anyway related to what you do for a living, and if there might be a conflict of interest, it might be worthwhile to include something like this:

The contents of this article reflect my opinions only and not necessarily those of my employer.

5) APPROVAL FOR *.ANSWERS - THE BIG TIME

5.1) Why bother getting a FAQ approved for news.answers?

When your FAQ is approved for posting to one or more of the *.answers newsgroups (news.answers, comp.answers, sci.answers, etc), it is brought to the attention of those who might not be regular readers of the newsgroup(s) that you usually post your FAQ to. This means that a larger potential audience gets a chance to know about your hard work.

One of the major reasons for getting your FAQ approved by the news.answers team, is that a FAQ that is posted to one of the *.answers newsgroups is automatically archived. This is important since some sites purge old postings more frequently due to lack of space. The archive makes your FAQ available anytime someone wishes to ftp it from rtfm.mit.edu (the archive site) or any of its mirrors.

Another important reason to get your FAQ approved, is that you can then use the faq-server to automatically post to whichever newsgroups you want.

Last, and least or most (depending on your personality), there is always the fame and glory associated with being a FAQ maintainer. Once your FAQ becomes widely read and distributed, you will be amazed at how many times your name will be mentioned in postings or other articles.

5.2) How do I get my FAQ approved?

In order to get a FAQ approved for posting to news.answers, you need to submit your FAQ to the *.answers team. For a detailed explanation of what you need to do to make your FAQ *.answers compliant, read the *.answers guideline. Check in news.answers to see if it is posted there under the heading "news.answers submission guidelines". If the document isn't currently available at your site, send a mail message to mail-server@rtfm.mit.edu with the command "send usenet/news.answers/news-answers/guidelines" (without the quotes) in its body. You can of course ftp the document from the same place.

Getting a FAQ approved is easy and doesn't require much on your part.
The most important consideration for approval is a proper header. A
minimal example follows:

```
From: russ@silicom.co.il (Russ Hersch)
Newsgroups:
comp.robotics,comp.realtime,sci.electronics,comp.answers,sci.answers,news.answers
Subject: 68hc11 microcontroller FAQ
Followup-To: poster
Approved: news-answers-request@MIT.EDU
Summary: This article is a collection of information sources on
the Motorola 68hc11 line of microcontrollers.

Archive-name: microcontroller-faq/68hc11
Posting-Frequency: monthly
```

This is a real live header taken from one of my FAQs. Another
example would be the header to the FAQ you are currently reading.
The news.answers guideline document clearly explains the purpose of
each line of the header. To make things simple, you can just take
the above example and adapt it for your FAQ. Just a few cautions:
- All of the fields in the above header are required and all must
be included. There are additional, optional fields which may be
included if you want to take the time to figure out what they're
used for. Personally, I'm too lazy.
- The Newsgroups line must have one space after the colon. All of
the newsgroups must be listed on one line with no spaces or
extraneous characters (which is why the Newsgroups line seems to
fall off the edge of this document - it is not a mistake).
- Followup-To must specify either "poster" (which directs followups
back to the author of the FAQ) as done above or the home
newsgroup of the FAQ (which directs followups to the newsgroup).
Do not forget this field since responses then might be directed
to the news.answers team, and they will not be very happy about
that. Do NOT put an E-mail address in the "Followup-To:" field.
- *** IMPORTANT *** The Approved heading is ONLY used when your
FAQ is actually approved. When you are notified by the
news.answers team that your FAQ has been accepted, then you may
add this line to your header. DO NOT include this field until
your FAQ is approved, or you will find yourself in deep doo-doo.
- For a multi-line summary, the second line of the Summary field
should start with at least one space.
- One blank line should appear before the Archive-name line.
- Archive-name should be fairly descriptive but short. If you
aren't sure about this, take your best shot at it and the
*.answers team will adjust it if necessary.

Once you've added the appropriate header to your FAQ, you can submit
it to the news.answers moderators for approval. Send it to the
following address: news-answers@mit.edu. Don't expect an immediate
answer as these guys are REALLY busy. They will send you back a
letter indicating if your FAQ has been approved, and if not, what

needs to be done to get it in order.

If you have any questions, don't be embarrassed to ask the news.answers moderators, that's what they're there for. Most of the time the problem is simpler than you think. As you gain more experience, things will become clearer. Send your questions to: news-answers-request@mit.edu.

To get your FAQ approved for posting to *.answers, you need to do the following:
1. Get (as described above) the "news.answers submission guidelines" article before you do anything. This is a good reference document which discusses many details that I chose not to delve into.
2. Make sure your FAQ is accurate. If you've already been posting it, then your readers have probably already helped you out on this. If you prefer, you can begin by posting the article marked as "DRAFT" a couple of times, to get feedback - then submit it for approval.
3. Make sure that your FAQ is organized so that the material is easily accessible to the reader.
4. Similarly, make sure your FAQ is formatted nicely (proper margins and indentation). This really helps when trying to read it.
5. Prepare a header (as described above) to add to the beginning of your FAQ.
6. Submit your FAQ for approval.
The address for submitting your article:
news-answers@mit.edu - ONLY for submissions (no questions!)
The address for requesting information and for asking questions about the process:
news-answers-request@mit.edu (questions and requests for help)
7. Please be patient and don't ask the moderators about the status of your submission. They are very busy and are not able to deal with "nuisance" mail. Use your judgement - if your teenage daughter was in Kindergarten when you submitted the article, then you might be justified in sending them a note. If she was only in fourth grade, think twice.

5.3) FAQ maintainers

Once your FAQ is approved, you are now included in the fraternity of elite individuals known as FAQ maintainers (FAQers might not be the best term for obvious reasons). Pass out cigars, throw a party, have a beer, and write and tell Mom about it.

So what now? Well, you should prepare yourself for Email. Possibly lots of it. You've now become a "personality" on the Internet (as Jonathan Horen, a good friend of mine put it), and an "authority" on the subject that your FAQ covers (whether you really are or not). You will more than likely become a central address for those who have questions about the topic that you've addressed in your FAQ. Enjoy

yourself - you will end up "meeting" a lot of very nice people from all over the world. These new friends of yours will help you keep your FAQ up-to-date. Everyone will benefit.

It is very likely that you will find yourself very busy maintaining your FAQ. Some FAQs require a lot of attention. Others, once they hit their maturity, just sort of coast for a while. My microcontroller FAQs keep me pretty busy and often keep me from working with the very microcontrollers that I originally set out to do. Since I'm still learning a lot about the subject, I don't mind this too much. However, I would like to apply what I'm learning and actually accomplish something. I wouldn't want anyone to say (to paraphrase an old saying), "Those who can do, those who can't write the FAQ."

5.4) FAQ maintainers mailing list

As a FAQ maintainer, you might want to consider joining the faq-maintainers mailing list. This is used for discussing issues related to the *.answers newsgroups and the maintenance of FAQs. There is also a faq-maintainers-announce list, which is used only for announcements. Subscribers to the faq-maintainers list automatically receive messages sent to faq-maintainers-announce.

Traffic on the faq-maintainers list is sporadic and the topics eclectic. Sometimes I feel that this mailing list is really useful, other times I have no use for it whatsoever. Lately, the traffic has been heavy and the topics varied, some interesting and some not so interesting (in my opinion). Try it out for yourself and see if you get anything out of it. You can always terminate your subscription if you don't find it useful (don't try asking for your money back though :-).

You may send a subscription request for either one of these lists whenever you want. Please send an Email request to faq-maintainers-request@rtfm.mit.edu with a short message in the body specifying which list you would like to subscribe to.

The faq-maintainers list is not restricted to only those who have [approved] FAQs that are posted to news.answers. Anyone who is interested in the fine points of FAQ writing/maintaining is invited to participate in the discussions. If you are considering putting a FAQ together, even if you don't intend on getting it approved, the faq-maintainers list is a valuable source of information, and a good place to ask questions.

6) ACKNOWLEDGMENTS

I would like to thank the following individuals who have helped and contributed to this document:
Jonathan Horen (a real personality in his own right) for his brilliant technical support and who has finally stopped calling me a Techno-Wimp just because I don't know UNIX

Pamela Greene, Ping Huang (a true gentleman and a scholar), Thomas Koenig, Aliza Panitz, and the rest of the news.answers moderation team for their valuable help in getting my various FAQs approved for news.answers and for providing important suggestions to this document
Mark Moraes (the news.announce.newusers moderator) for his valuable contributions and continuing support
The subscribers to the FAQ Maintainers mailing list who from time to time provide valuable insight and who are always there when help is needed
Mark Israel (the maintainer of the alt.usage.english FAQ) who pointed out a lot of errors a long time ago that I finally got around to fixing a short time ago!
Carl Aude for his suggestions about copyrights.
You, my readers for your support and encouragement, I'm glad I was able to help
My three rug rats (son Menachem, and daughters Michal and Edya) for your "Frequently Asked (stupid?) Questions" :-)

Special thanks to my Mom and Dad (Gloria and Morton Hersch) who never hear from me because I'm always busy with my FAQs. I'm writing a FAQ about myself to send to them, so they'll know what I'm up to.

I disclaim everything. The contents of this article might be totally inaccurate, inappropriate, misguided, or otherwise perverse - except for my name (you can probably trust me on that).

Copyright (c) 1995 by Russell Hersch, all rights reserved.

Given your criteria, I'd have to agree with you. HOWEVER... I've used VNC plenty, and there are numerous minor 'quirks' where parts of the screen don't get updated correctly. For connecting Windows machines to other Windows machines, the Microsoft 'Remote Desktop' facility is, in my experience, more reliable and robust (it lets you control far more of what gets 'stripped away' from the controlled machine, besides just the desktop wallpaper that VNC will). (The server side is included with Windows XP for the price of the OS, and the client is free for all platforms, including UNIX machines.)

VNC does have some nice goodies that remote desktop doesn't -- the built-in 'web server' feature is really great. I've run some Windows machines with both VNC and remote desktop enabled.

Don't you ever change the record, amateur radio is what you make it, it's only a hobby, if you spent less time moaning and more time in the shack working the bands and actually putting into practice some of your bullshit you may find out what this hobby is all about.

Do talk again, from when I was a child I talk to God.
Just forgot it for a decade when I was grown up.
That was the most misserable time in my live.
Talk positive, positive=live, negative=dead.
The power of words !
The good news is, you can program yourself.
There are too many negative "things" around here.
Any questions? think about TV advertisement.
If words of someone else can do let you buy, than the
same method can work for you !
All the negative things take something from us.
The live out of us, believe me.
You can't start your car battery for ever whitout
charge it.
If you talk positive you will receive positive things.
God made live=positive, believe in it and carry it with you.
Everyone on this earth likes friendly, love.
I make a stronger statement, no one can whitout love.
No money on this world can buy you that.
Samples enough!
Multiply the good things in you, that's the message of God.
And that are just the hard things!
It's much easy'er doing nothing getting old and going dead.
But what was the purpose of that?
Beeing here and leave the world whitout making it a little better?
Your be born for nothing? Would you?
My personal believing is, be here and make something out of it,
else jump off a high building.
Would get you only in more trouble.....

Why I would have a dialog with God so as I said, "We could talk".
That's just a wish, and personal.
Some day I will have my dialog, I am very sure about that.

I could not let ending this thread with, I stopped going to Church.
Whitout this notice.
Its your choice and I will respect that.

I not going to any Church too, but don't stop talking to God !
If this message does not make sense..... just skip it.

I am not sure exactly what is trying to be accomplished here but if it
is to combine two different bandpass filters then yes a T. The cable
from the low pass filter to the T should be a quarter wave length at
the frequency of the high pass filter.

The cable from the high pass filter to the T should then be a quarter
wave length of the low pass filter.

The low pass filter will look like a short circuit at the high pass
frequency. With the quarter wave length cable that short circuit will
then be transformed to a very high impedance to the hi pass circuit.
That effectively isolates one from the other.

Do the another T and cable setup at the input and output.

If I understood the O/P he was trying to split and then recombine the 25-3000 band with a split ("crossover") at 500 MHz. Assuming a 50R in/out impedance across the passband, the fiter sections presumably present a substantially different (usually much higher) port impedance out of band. A simple T combiner therefore presents a minimal impedance mismatch except near the split frequency.

Also I'm still thinking about how to make a quarter-wavelength line at 25-500 MHz or at 500-3000 MHz..

Win,

What you are asking for are the QST articles authored by Rick Measures.
"Circuit Improvements for the Heath SB-220 Amplifier" (Rick's updated
manuscript (2001) for Nov.-Dec., 1990 QST article).
http://www.somis.org/SB220ci.html

Rick has these on his web site, here:
http://www.somis.org/

Usually a bandpass filter will present a low impedance out of band.
That is where I was with the quarter wave cables. But you are right,
it may be somewhat of a problem with that wide of a span. Guess I
didn't read close enough.

I read the original post again and maybe understand better what is
trying to be accomplished.
With the back to back diplexers there may be a termination problem
with combining them. ?? Maybe try a load resistor at the junction
where they recombine.

The simplest solution seems to be two hybrid power splitters back to
back. No band pass filters needed. Like two tv cable splitters. Of
course that means 6 db of loss.

Fine, so it's a technical hobby that requires some aptitude and an interest in one or more facets of the hobby/technical pursuit. I may be more towards to the technical side of the hobby and have an interest in restoration of old boatanchors but there are many other areas of interest. If a licensed amateur is interested in contesting/collecting squares, ragchewing, homebrewing raynet or even trying something new why not just let them get on with it. Garath has a bad attitude mainly directed at anyone without a Morse test, more a case of "I spent 10 long years learning the code, it was hard work so why should they get HF by just passing the RAE." Morse is a fantastic mode for DX and weak signal working breaking down the language barrier and allowing for very simple homebrew but is not a suitable or appropriate qualification for access to HF (the requirement for Morse was due to the shared bands to enable the primary user the facility to tell us to QSY, no longer necessary). We all have our personal views regarding the qualifications that should be required, usually the skill level of the individual expressing the view, in your case Walt probably 30 wpm+. My view is that a higher level of RAE pass mark should be required but that again is just a personal view. Don't deride the amateurs, deride the system if need be but blind insults towards a licence "CLASS" are out of order and to coin a phrase from Garth are not in keeping with the gentlemanly traditions of amateur radio.

Im tellin yah it workx and its so worth it

Turn $5.00 into $50,000...read this to find out how!!!
READING THIS COULD CHANGE YOUR LIFE!!!
I found this on a bulletin board like this one and decided to try it.
A little while back, I was browsing through a newsgroup, just like you are now, and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $5.00! So I thought, "Yeah right, this must be a scam", but like most of us, I was curious, so I kept reading... I also did an internet search and found nothing but success stories.

Anyway, it said that you need to send $1.00 to each of the 5 names and address stated in the article. You then place your own name and address in the bottom of the list at ..5, and post the article in at least 200 newsgroups. (There are thousands) No catch, that was it. So after thinking it over, and talking to a few people first, I thought about trying it. I figured "what have I got to lose except 5 stamps and $5.00, right?"

Then I invested the measly $5.00 (I use the word "measly" because $5 really is measly compared to the money I have made through the initial investment). Well GUESS WHAT!!... within 7 days, I started getting money in the mail! I was shocked! I figured it would end soon, but the money just kept coming in.
In my first week, I made about $25.00. By the end of the second week I had made a total of over $1,000.00! In the third week I had over $10,000.00 and it's still growing.

This is now my fourth week and I have made just over $42,000.00 and it's still coming in rapidly. It's certainly worth $5.00, and 5 stamps, I have spent more than that on the lottery!!
Let me tell you how this works and most importantly, why it works....
Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it.
I promise you that if you follow the directions exactly, that you will start making more money than you thought possible by doing something so easy!

Suggestion:
Read this entire message carefully! (print it out or download it.)
Follow the simple directions and watch the money come in! It's easy.
It's legal. And, your investment is only $5.00 (Plus postage)

IMPORTANT:
This is not a rip-off; it is not indecent; it is not illegal; and it is virtually no risk - it really works!!!! If all of the following instructions are adhered to, you will receive extraordinary dividends.
PLEASE NOTE:
Please follow these directions EXACTLY, and $50,000 or more can be yours in 20 to 60 days.
This program remains successful because of the honesty and integrity of the participants. Please continue it's success by carefully adhering to the instructions.
You will now become part of the Mail Order business. In this business your product is not solid and tangible, it's a service. You are in the business of developing Mailing Lists.
Many large corporations are happy to pay big bucks for quality lists. However, the money made from the mailing lists is secondary to the income which is made from people like you and me asking to be included in that list.
Here are the 4 easy steps to success:

STEP 1:
Get 5 separate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST."
Now get 5 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (to prevent thievery).
Next, place one paper in each of the 5 envelopes and seal them. You should now have 5 sealed envelopes, each with a piece of paper stating the phrase "PLEASE
PUT ME ON YOUR MAILING LIST.", your name and address, and a $1.00 bill.
What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL!
You are requesting a legitimate service and you are paying for it!
Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office (1-800-725-2161) and they confirmed that it is indeed legal!
Mail the 5 envelopes to the following addresses:

..1) Jason R
3702 Werner Ave.
Austin, TX 78722

..2) J Arenas
1600 Malibu
Carrollton, TX 75006

..3) Richonda S
CMR 402 BOX 274
APO, AE 09180

..4) J Roth
2901 Barton Skyway ..3406
Austin, TX 78746

..5)Jesse James
1778 Swift Ave.
Ventura, Ca 93003

STEP 2: Now take the ..1 name off the list that you see above, move the other names up (5 becomes 4, 4 becomes 3, etc...) and add YOUR Name as number 5 on the list.

STEP 3: Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups. (I think there are close to 32,000+) All you need is 200, but remember, the more you post, the more money you make!

This is perfectly legal! If you have any doubts, refer to Title 18 Sec. 1302 & 1341 of the Postal lottery laws. Keep a copy of these steps for yourself and, whenever you need money, you can use it again, and again.

PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions.
Look at it this way. If you are of integrity, the program will continue and the money that so many others have received will come your way.

NOTE:
You may want to retain every name and address sent to you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.)
So, as each post is downloaded and the directions carefully followed, five members will be reimbursed for their participation as a List Developer with one dollar each.
Your name will move up the list geometrically so that when your name reaches the ..1 position you will be receiving thousands of dollars in CASH!!!
What an opportunity for only $5.00 ($1.00 for each of the first five people listed above)
Send it now, add your own name to the list and you're in business!

---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS----------
Step 1)
You do not need to re-type this entire letter to do your own posting. Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this document, and select 'copy' from the edit menu. This will copy the
entire letter into the computer's memory.
Step 2)
Open a blank 'notepad' file and place your cursor at the top of the blank page. From the 'edit' menu select 'paste'. This will paste a copy of the letter into notepad so that you can add your name to the list.
Step 3) Save your new notepad file as a .txt file. If you want to do your postings in different settings, you'll always have this file to go back to.
Step 4)

Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, message boards, chat sites, discussions, etc.)
Step 5)
Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this
will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button.
You're done with your first one!
Congratulations...THAT'S IT!
All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup!
REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200
That's it! You will begin receiving money from around the world within days! You may eventually want to rent a P.O.Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it.
JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.
Now the WHY part:
Out of 200 postings, say I receive only 5 replies (a very low example). So then I made $5.00 with my name at ..5 on the letter.
Now, each of the 5 persons who just sent me $1.00 make the MINIMUM 200 postings, each with my name at ..5 and only 5 persons respond to each of the original 5, that is another $25.00 for me, now those 25 each make 200 MINIMUM posts with my name at ..4 and only 5 replies each, I will bring in an additional $125.00!
Now, those 125 persons turn around and post the MINIMUM 200 with my name at ..3 and only receive 5 replies each, I will make an additional $626.00!
OK, now here is the fun part, each of those 625 persons post a MINIMUM 200 letters with my name at ..2 and they each only receive 5 replies, that just made me $3,125.00!!!
Those 3,125 persons will all deliver this message to 200 newsgroups with my name at ..1 and if still ONLY 5 persons per 200 newsgroups react I will receive $15,625,00!
With an original investment of only $5.00! AMAZING! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $5.00 to names on the list, putting your name at number 5 again. And start posting again.
The thing to remember is do you realize that thousands of people all over the world are joining the internet and reading these articles everyday?, JUST LIKE YOU are now!!
So, can you afford $5.00 and see if it really works?? I think so...
People have said, "what if the plan is played out and no one sends you the money? So what! What are the chances of that happening when there are tons of new honest users and new honest people who are joining the internet and newsgroups everyday and are willing to give it a try?

Estimates are at 20,000 to 50,000 new users, every day, with thousands
of those joining the actual internet.
Remember, play FAIRLY and HONESTLY and this will really work!!!

Doesn't it say in the licence conditions that the licence is for the self
learning of the licensee?
or are you saying that everybody should know absolutely everything about
radio before you can even get a licence?
Didn't you also learn about radio!

: again is just a personal view. Don't deride the amateurs, deride the system

as i said before on this newsgroup.

the poor m3 candidate is ''taught'' and then fed to the cannons in some
sort of ''pump-em-out'' activity to flood amateur radio with
raw-green-beginners in some sort effort that apparently is to lower the
standard and to turn 7mhz into 27mhz.
these unfortunates are then faced with the views of those who know
that the system sucks. these people being those who are not beholding to a
system that requires an rsgb instructor to sign a piece of paper before
they can get a licence.

but as i sad before, m3's themselves should shout for a higher standard.

as i said before...the system is being run by people who refused to
recognise the morse test but now force every candidate to do the morse
assessment!

thats a double-standard if ever there was one.

I recently built a 100W HF amplifier by modifying existing designs.
Now I'd like to build an automatic antenna tuner. Where can I find some
good articles / web sites on theory, practical design, and tuning
algorithms for the switching circuit. Has anyone published all the
details including source code.

QST published a (two-part?) article on an "Easy Tuner" design a couple
of years ago. As I recall it's a microprocessor-controlled tuner of
the T configuration, with a switched tapped shunt inductor, and two
air-variable series capacitors driven by small motors.

I believe that source code was available.

I suspect that most of the ATU-control code out there is proprietary,
and that which isn't is likely at least somewhat specific to a
particular ATU design. Designs using motor-driven capacitors are
going to be at least somewhat different from those which use
relay-switched capacitor sets.

How do I design an automatic antenna tuner with no moving parts?

This is a good question.

How to do it - without relays, motor driven capacitors and inductor cotacts?

To make any tuner variable, you have to vary something (and this can
only be an L or a C).
If you don't vary them physically with moving parts, you have to vary
them electrically.
You can change C using Varicap diodes (where you vary a DC voltage.
You can change L by using inductors with cores which you can partially
saturate by varying a DC current.
Neither technique is really applicable to transmission.
Ian.

1.) Since you did not specify the power level, use varactor diodes and
inductors on a suitable core material and vary the core permeability
with an external magnet field, controlled by a variable DC-current.

2.) Alternatively, get rid of the antenna tuner by using resonant and
matched broadband antennas.

Hi folks,
I am just finishing up a Ten-Tec Model 1254 receiver.
Originally, this unit used these devices, but now, they have thrown in some substitute.
Does anybody know what the on resistance and minority carrier lifetime of this device is? I've got a batch of 1N5767s, which have a minority carrier lifetime of 1.5uSec. How do they compare? Can I use the 1N5767s in place of the Ten-Tec diodes?

Pete

Here is a link to the original 1996 QST article on homebrewing a tuner called the AT-11. It is now made by LDG Electronics. It uses relays to switch inductive and capacitive elements in an L-network tuner configuration.

http://www.3764.net/qst/1996-1999/automatic_tuner_at11.pdf

The article presents the complete schematic and theory of operation, but there is no microprocessor source code included. The author does say that you can but a programmed chip from him, but I don't know if that's still available. Maybe someone in this group can suggest where to get source code or a hex file of the object code.

Sounds like the mental illness of living in the world of make believe to me.

If anyone else went around claiming that there was an invisible parrot
on their shoulder that had all the attributes of this imaginary, "Jesus",
they'd
be very quickly carted off to the loony bin. Why is it any different for
the religionists who are very obvious loonies?

Why should one mental illness, religion, be any more socially acceptable
than others......look at all the death and destruction that has been wrought
upon the world by that religious loony Dubya!

The best software for any self-respecting _REAL_ Radio Ham is
that which he writes for himself. It is CBer who buy such things
off-the-shelf.

It is very much the case with software that you can manufacture a much
better
product than any you can buy for a very small percentage of the cost.

Sussed it 'They' like to be thought of as 'special. I am a radio amateur. I am special.
Then loads of other people realise, there not so special after all, anyone can do it!
As there are now a 'new' breed of sharing radio amateurs, who after years of secrecy are willing to break ranks and tell the less fortunate, the radio secrets. Show them how easy it is to start on the path, to be a radio amateur. The new interested party's take some 'tests' and find them so easy, that they all pass. They are 'baby' radio amateurs, the idea is they learn as they go, pass exams and eventually become full licence radio amateurs.

The old school will never accept it.
Who likes to work and pay for something, then see some one else get it for less?
No one its not human nature.

The Masons will never think the Buffaloes are up to being Masons.
If they dropped all the secrets and made it easy for them to get in.
There would always be a section who moaned about it.
Even if the Buffaloes brought in loads of funds, did loads of good work.
They would always be 2'nd class Masons.
(To the Masons)

The rest of the world don't give a fig!

The older radio amateurs would like to stay special, the elite.
Then someone decided they had been top of the class long enough.
The Ofcom and RSGB are both business, businesses can't afford to be choosy with there clients, can they?
If radio amateur numbers had not increased and they had not received more revenue.
It wouldn't have paid its way, eventually they could have sold it off.
The CB 'licence holders' carried it for years, there numbers paid for the rest of the 'hobby' radio spectrum.
Now that's going, this is another way of getting the hobby radio users paying for our bit of the radio spectrum. If we cant pay for it they will sell it some one else, because to them, its not personal, its only business.

I'm not so sure that is really all that off the wall.

Most autotuners are pretty mindless ... you only need to get down to a "reasonable" SWR, so you can use a finite number of LC circuits. Most tuners count frequency (easy) and use that to look up where they were the last time they were near that frequency, so they randomly try everything at first, but then use their experience to get there quicker the next time. A few actually look at the phase angle to figure out which way to go, but they are in a minority and it isn't all that clear that they do much better than just guessing.

Typically, relays are used in commercial autotuners. Latching relays are simple, cheap, and require very little power. But I can see no reason why one couldn't use PIN diodes if the "no moving parts" was a requirement. It would ratchet up the price a bit, and probably also the power consumption, so I can see why it wouldn't be a common commercial approach, but if the no moving parts limitation is a hard requirement I can't see why it wouldn't work.

I would also think about the "why" on the no moving parts. Something like PIN diodes is going to mean constant power consumption, which in turn means constant generated heat. It isn't obvious to me that this will result in better reliability than latching relays, which are pretty darned good these days as far as reliability is concerned. It will also end up (I think) increasing the parts count quite a bit, which again will hurt the reliability, to say nothing of the cost.

..

Good description. The bit you missed is that those who always seem to rant
about how hard it used to be are usually the least technically able.

First time I've heard that expressed. There are actually a whole range of
such organisations, Round Table, Rotary, Loins, Odd Fellows, Ancient Order
of Forresters, Masons (mainstream, female, and mixed), ... All no
doubt some members each of will think 'their's is the best', truth is,
most are much the same and many have surprisingly similar aims. At the end
of the day, if you find one you enjoy then it is the best for you.

> The rest of the world don't give a fig!

But some decide to make an issue of it.

I'm looking for design (or at least pointer to some information about)
for a switching power supply that would provide about 1KV @ 2A given
110/220VAC input. A commercial product would work too, but I've never
seen such a thing. It need not be regulated, but I would want it to be
switching (to reduce weight/size.) I am having trouble getting started
on my search for information.

Source record: 20286

As others have noted, it's certainly possible to do with the only moving parts being relays -- there are several commercial tuners on the market in this category.

But it'll be awfully tough to replace the relays, if your intention is to transmit. Relay contacts have very high impedance (low capacitance) when off, and very low resistance when on. They'll handle very large voltages and currents. And the impedance, both on and off, doesn't change with applied signal level. There isn't any other component that has all these characteristics, and some or all are required in a wide range tuner. You might, by very careful analysis of the circuitry under various load conditions, come up with some sort of switch (e.g., PIN diode, VMOS FET, etc.) which can handle the voltages and currents at each switch point, while having acceptable on resistance, off capacitance, and linearity (non-variation with signal level). But it won't be a simple task. And you'll probably still have to sacrifice some efficiency and tuning range.

In a receive-only tuner, you still have the problem of getting adequate on and off impedances, but you are relieved of the voltage and current requirements.

Relays are just simply very hard to beat for some applications -- and this is one of them.

Of course, you can try varying the L and/or C by a number of methods, such as others suggested -- using saturable reactors for L and varicaps for C. Again, though, you run into voltage and current limitations. And these devices tend to be nonlinear -- that is, the L or C depends also on instantaneous signal level. So when they encounter a large signal, they create distortion which produces harmonics. This would be a fine approach for a receive-only tuner, but not a good one if you want to use it for transmitting.

So, that's how you do it. Good luck!

Hi Dave,
QEX had an article in the February 1991 issue by W9QQ about such a
beast, with a corrigendum in the August '91 issue and a comment in the
December, '91 issue.

I was well along in the paper phase of a design when I saw an ad in QST for
http://www.wattsunlimited.com/
where you can get a kit or assembled HV switching supply. They claim
1.1 amps at 2500 VDC, you could probably wind the secondary for 1 kV or
have them do it for you.

I haven't sunk the money in it yet, other things getting in the way but
it looks like an easy way to get HV at an amp or two.

Secret Marconi Day Station - South Dorset Radio Society

Just to let you all know that the South Dorset Radio Society will be running a Marconi Day special event station from the little known Marconi site at Portland Bill. The site was used by Marconi to make first contact with Gibraltar.

It is so secret that the members don't even know about it yet and the RSGB have not published details of the special callsign. This is due to the fact that they don't want the Portland club knowing that they are invading for the weekend. So SSSSHHHH! Don't tell anyone.

1158. WTB: OCXO, 20-120MHz

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-02-21 01:42:52 UTC
From: "Odd Erling N. Eriksen" <odderi@pvv.org>
Message-ID: <cvbeas$9hq$1@orkan.itea.ntnu.no>
Source record: 20291

Hi,

I am currently in need of a very stable, low phase-noise oscillator for use in a 1296MHz beacon project.

The PLL I intend to use (ADF4007) can run its PFD at up to 120MHz, so taking advantage of this to keep the phase noise contribution of the OCXO reference down + provide simpler filtering of the reference spurs is a high priority. The higher the OCXO frequency, the happier I am. :)

Supply voltage/current consumption/packaging is not important - most important is to find a good reference which will not shoot my budget down in flames.

So - does anyone have something which may be of interest in their junkboxes, as well as being willing to ship internationally? (To Norway, to be more precise. :)

TIA,

They do exist - I'm in the process of doing some restoration on an old Singer tone generator which does arbitrary pairs of frequencies.

These days, the easiest way to create a tone combination is usually to use PC software. Generate two sinewave tones at the two frequencies you want, with 50% amplitude or less, then mix 'em with the appropriate relative amplitudes. There's lotsa free software which will do this - e.g. Audacity on Linux and no doubt many others.

You can then play the mixed file out through your PC sound card, or burn it to a CD-R and use a portable CD player to reproduce the sound... whichever is most convenient. In either case, feed the line-level output signal to a fixed or variable attenuator to get the voltage level you need.

What modes are you planning to use ? CW only or some other digital
modes intended for EME ? Is the 432.000 - 432.025 MHz tuning range
enough ? Which end of the link is responsible for compensating for the
lunar doppler in each particular mode ?

If you are only operating at a very narrow segment, a VCXO could be
enough and get away with the synthesiser noise. A 12.9 MHz VCXO
followed by a tripler would generate the 38,7 MHz, which could be used
to mix down to 10.7 MHz IF. The required crystal pulling range for 25
kHz wide reception range would be about 650 ppm.

The doppler requirement may require that you must be able to operate
split, so two VCXOs would be needed.

A Square Wave is all the harmonics of the fundamental, so a 1.9kHz square wave will have all the harmonics which will complicate the measurement --

If you take a square wave and filter it you can get a relatively low distortion fundamental -- it's much easier than you might think -- use an NE556 dual timer to generate 1.9kHz and 1.3kHz square waves, combine with 10k resistors into an opamp buffer, filter with an MF-10 (now upgraded to LMF100) switched capacitor low pass filter -- voila.

For the past several years I've irregularly posted my experiences ordering over the web from several catalog houses/surplus suppliers with online ordering.

My hope in doing this was not just to give pointers to other small-timers like myself as to which ones are the best sites, but to give feedback to the companies to get them to improve their interfaces.

But since my first online order (1997 or so) one outfit has risen way above the others: Digikey. Digikey's website leaves all the others in the dust. Their search engine and selection forms for picking out components is simply superb, and is getting better all the time. If I want to know what X5R dielectric capacitors are available in 0402 form factor, the answer is just a couple of clicks and a few seconds away. This is simply amazing.

Semiconductor search is not quite so slick, but I cannot blame Digikey for not trying. They do a good job, especially seeing as how 7 different vendors describe their similar parts with slightly different wording. For product lines where categorization and selection menus might be able to work well, they've coerced everything into selection menus that are simply superb. And datasheets and sometimes photos are always just a mouse click away for the real comparison.

Don't get me wrong: Newark, Mouser, Allied, Jameco, and a few others that I order over the web from have pretty good web-order-entry systems. They've all improved since they first began taking orders over the web. Many of them now have near-real-time stock and shipping status. They let me do my hobby shopping at home at night without having to call during the day. But they have pretty much zero search and selection ability.

Digikey, keep doing it right!

Tim.

Have a look at the Farnell and RS websites (UK):

http://uk.farnell.com/jsp/home/homepage.jsp

http://rswwww.com

I prefer them to DigiKey.

Leon

And why not start with a sinewave oscillator in the first place? That's
the way it used to be done, two transistors each making up phase shift
oscillators.

A sqarewave won't complicate measurements, it will downright give
different results. The whole point of two-tone testing is that the
first tone causes a "carrier" out of the SSB transmitter (the single
tone translates to an RF frequency), and the second tone adds modulation.
If the tones aren't pure sinewave, the output of the transmitter will
be radically different.

Hi,

I agree entirely about DigiKey. However, when I want to order just a
few parts (rather than dozens at a time), Mouser has a much better price
for small quantities. Also, they will ship via 1st class mail - saving
on shipping costs.

So I use the search on DigiKey, check the price, then search by the exact part number on Mouser to see if the price is much lower.

That's an interesting perspective, Tim. I find it easier to search Digikey for passives and Mouser for semiconductors/actives. Jameco has them all beat for their specialties like wall warts, motors, solenoids, solar stuff, and tools/solder stations.

That's my triumvirate...they all have stuff they do best, and I really have no need for other catalogs to cobble up the bench.

For onesie, twosies they all have about the same prices, but when you start buying in thousands, Mouser has them beat by a mile.

A square wave oscillator followed by a filter is, in some ways, easier
to implement than a phase-shift oscillator -- particularly if you want
well controlled frequency and amplitude without having to use
sophisticated AGC circuits.

That's probably why the guy doesn't advocate using it: he's recommending
a square wave that's heavily low-pass filtered to get rid of the
harmonics. If done right this will result in a clean stable sine wave
at the desired frequency.

Their pricing doth truly suck sometimes, but on the good side they stock most of the stuff in their catalogs (and then some), as opposed to some "other" distributors whose catalogs might be characterized as vaporware.

I wonder sometimes how much they spend printing catalogs every two months, which always seemed excessive to me. I'd have thought twice a year would be plenty.

Yep. To add to the other reponses, there are two-tone audio
generators used for two-tone control testing of commercial gear.
I've got one from my dad's estate that does two-tone-sequential
with adjustable duration for each tone, and two-tone-combined, and
single-tone. Thumbwheel freq(s) select from <100 cps to 9.999 kcs.
Pot adjustable tone durations (and delays), and levels.
It's probably 15-20 years old: Automated Industrial Electroncis
Corp., Model 2TSG-1.

They must show up on eBay from time-to-time. Google claims several
'hits' there -- but a search on eBay at this time shows none.

Hi all I am helping a friend promote a web site. You see a childhood friend of hers lost her husband at the World Trade Center on Sept. 11, 2001. She has run into some hard times and my freind wants to help her. So she came up with the idea to market Just say NO to Bin Ladin dartboards and punching bag covers. Not only is she going to donate part of the proceeds to her freind but an additional part of the proceeds will go to the Firemans Fund. If you could take the time to check out the web site it would be much appreciated!! The web site addy is:

Hello all,

I'm currently studying code so I can pass my General class license test. I am also interested in homebrewing and QRP. I am looking for plans for building a homebrew 6 meter transmitter. I know that the propagation is not favorable for 6M right now, but until I gain my General class license, I think such a project will be a good place to start. I would appreciate any help that you can offer. Thanks.

Yes. For this, they might benefit from hiring a person with some real
electronics knowledge, who might be able to standardize the terms used
in the database, and thus would have to translate any non-standard
compliant terminology from their vendors into the terms used in the
database. That would make even the semis consistent.

Good day!

Farnell took Newark over a few years ago.

OK, that explains it :-).

Newark always had some interesting semiconductor stock from HP (now Agilent... too many name changes!). Finding what they have in stock is certainly easier now that I can search on the web, but I'd probably buy more from them if they improved their web interface so I didn't have to type in every single part number that may be useful to me just to see if they carry it.

I just tried Newark/Farnell for some passive searches and indeed they've recently updated their search interface so that it's a lot like Digikey's.

Tim.

Oh, so we can be sure that you wrote the operating system and mail program
that you are using to access the newsgroup? Or do you have no self respect?

Perhaps you have enough time to generate the software for the rest of us
that don't have the time to spend even more time coding than we have to
already. Unless you are a professional coder, then don't disrespect the
profession by suggesting that anyone can hack up a program for lower cost
with better performance. If you are a professional coder then considering
your posts, perhaps anyone could output code that is better than what you
are being paid for, so anyone could produce code with better performance
than what you can output.

If you are a professional at anything, then stay with your field of
expertise. Can you cite any accomplishments that you have achieved?
thanks, John.

That two tone generator is only two sequential tones. It will not
produce two tones at the same time. It is also pretty much of a square
wave coming out of it too. No good for ssb testing.
It was made for pager testing.

Negative.

The US FCC regs require the 5 wpm Morse for General and for Extra.

The lowest license class of the three, Technician, does not require
Morse. However, any licensed Technician who has also passed the 5 wpm
Morse can add privileges on HF in what used to be called the Novice or
Tech Plus bands.

Well, I would take minor exception to the statement that 6M is not so good right now. We have nearly daily openings from the upper midwest to the Rockie Mountains and the Gulf coast via sporadic E openings. Aurora enhanced operation is somewhat limited lately. That is why 6M is called the "magic band". It can open at noon or 9PM on Monday, Thursday or Sunday...or not at all for several days...

It has been and probably always will be my favorite band!

For those who joined the hobby after the early 70's let me point out
that DigiKey's name comes from an electronic digital keyer that the
company sold via ad's in QST. It was a small circuit board (about
2"x2") using RTL (IIRC) Ic's. After a few years the company transformed
from ham radio stuff to a part's mail order biz. Digikey didn't forget
their ham radio roots, they are happy to sell parts in onezes to

hobby buyers today.

I wrote that facetiously but I was really hinting of using a pc
soundcard. A sound card can produce very pure sinewaves from its FM
generator IC and most can play many dozens of notes at a time.

A*s*i*m*o*v

One thing that might be interesting to study is to get some commercial (surplus) product having 200-400 V secondary and adding some voltage multiplier stages after it. At frequencies well above the mains frequency, quite small capacitors are required in the voltage multiplier.

Depending on the multiplier chosen, the primary switcher should either be symmetric (push-pull) or asymmetric. Due to the limited isolation voltage between the primary and secondary, it might be a good idea of choosing a multiplier configuration, in which the secondary is close to ground (e.g. one side or CT grounded). As with all switcher rectifiers and capacitors, great care is required in selecting components with sufficiently low ESR at the actual operating frequency and low inductances, otherwise they might explode.

>A piano even does semi-tones... 10 at a time, 11 if you use your nose!

With some kind of PC, search for a program that can generate multiple tones (e.g. some electronic instrument imitations) or use two programs capable of generating a sine wave and mix them together with the PC's audio mixer and run the combined signal to the sound card output and to an audio amplifier.

The hardest part is getting some kind of calibrated output level.

One way of doing this with very simple test gear would be to put a low impedance 40 dB attenuator between the audio amplifier and the mic input.

Using a single 50 or 60 Hz sine tone from the sound card and a DVM at the amplifier output, adjust the amplifier output voltage to 300 mVrms, the microphone input will now be 3 mVrms. It is important to use 50/60 Hz, since a typical DVM frequency response would be quite bad at 1.3 or 1.9 kHz.

Now turn the 1.3 and 1.9 kHz tones on and make the transmitter adjustments.

That's pure nonsense. I've tried to get specialized semi's from both, and having failed that, I've found what I needed at other online sources. One recent example comes to mind: Futurlec. www.futurlec.com has a number of things much cheaper than D-K or M - and they're international.

Another is ultrabright LEDs. D-K or M have nothing worthwhile. You have to go to another supplier to get 'em.

And maybe the best example is the source(s) of many of our small qty parts: Ebay. ;-)

But on Ebay, read *all* the info in the auction. I see shysters, especially foreign shysters, who will sell you parts dirt cheap, and rip you off with the shipping/handling. :-(

I wonder how long Mouser can keep up the quarterly catalogs. They are getting huge these days! About 3 times the size of what they were just 2-3 years ago.

I'm not griping mind you, but I'd hate to have to do all my daydreaming and parts selections online.

Those janitorial supply guys have *really* high prices. Between
telephone directories, Mouser, Digikey, trade rags, paper packing and
EEM, the recycling box is never hungry. A few printouts don't amount
to much, and the few newspapers tend to get used for packing, which is
lighter than that recycled paper packing that Digikey uses.

Best regards,
Spehro Pefhany

> Have a look at the Farnell

I spent some time playing around with the Farnell/Newark web selectors
and they actually are pretty decent. Just like Digikey, they sometime
get tripped up by obscure numbering (for example, Newark/Farnell
calling 0603 size SMT parts 603 in many instances) or other gotchas,
but in principle the two mechanisms seem to be approximately
equivalent.

So, attaboy Newark/Farnell! Maybe they'll get more than one order
every 5 years from me now :-)

Tim.

You've got to be kidding. I find the RS website impossible to use. I
always refer to the printed catalog. Also they want me to register to
access data sheets etc.

Of course it's easy to just punch in a part number and get taken to the
appropriate result. But if you're searching a bit less specific -- say,
for a certain kind of connector you've seen somewhere, everything falls
apart because there's no such thing as a parametric search engine. Turning
tha pages of the paper catalog is much quicker.

>KI4GMX

Ok go for it. There are openings on 6m even now, maybe less frequent
but they are there. I've only worked Florida and Alabama twice this
last week on 6w and 4 elements at 31FT from Massachusetts. Actually
6M is a fun bad and when it opens it can be amazing. It's possible to
do real DX. I've worked 7 countries so far at low power. In a few
years when the cycle starts toward peak again it should be
interesting.

Now heres a suggestion for a project, or more correctly a series of
them that will get you on 6m.

An inexpensive transverter kit from 20m to 6m from TenTec 1208
139$ US. This will get you 8-10w on 6m, plenty believe me with an
inexpensive 3 element beam as high as you can get it. Come to think
of it, you could build the beam too!

The second part assumes that once you have the code and general
license you want a HF rig for use.

Now you need a 20m SSB transceiver, either a used commercial one or
build one. You can find pleny of HF radios that do low power that
either have 6m already or need the transverter to get there. There
are several kits that are candidates. Note: that transverter does not
require much power (under 5w) from the 20M rig so something that only
does a few watts is ideal. There is also a design on the net, see:

http://www.phonestack.com/farhan/

It's a build it from scratch but do able if you've built some before
and can get assistance. Why build a 20m rig and use a transverter?
Simple working with RF at 20m is far less critical than at 6m and
the transverter kit has a nice board that removes that problem.

Finally, even as a no-code tech you can use code! Just remember send QRS if they are too fast. So 6m can be used to practice and gain skill. There are a bunch of low power 20m CW only tranceivers that would drive the TenTec nicely. Most of them will recieve SSB but your limited to CW transmit.

As I said some suggestions.

The nice thing about Farnell is that they don't charge for normal delivery
and I usually get what I order the following day. That's in the UK, of
course.

1212. pumping the T2-exciter board with a squarewave signal

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-02-22 16:58:31 UTC
From: andreas magun <achmagun@bluewin.ch>
Message-ID: <421b643a$1_1@news.bluewin.ch>
Source record: 20243

Hi,

I have assembled a T2 phasing exciter (KK7B) and looked
at its output spectrum with a spectrum analyzer.

When pumping the exciter with quadrature sine wave signals it
works as expected (output power roughly 3 mW, sideband supression
better than 40 db).

However, when pumping with quadrature squarewave
signals of approximately the same power, the output power
drops by a factor of at least 20 db! I would have expected
much more power, similar to that obtained with sine wave pumping.

The quadrature phase signal was generated with a 74F74, the
quadrature signals being attenuated to give a power of approx. 10 dbm
and output impedances of approx. 50 Ohms.

There must be an explanation.

Thanks
Andreas

Right you are!! My apologies!
I just fired it up and verified: 2-tone, combined is _not_ an option.

(Damn! The older I get - the more wrong stuff I remember...)

One way to 'fix' a square wave is to push it through one or more
audio transformers.

Automated Industrial Electronics had an option where you could tie two of those boxes together and generate two tones at once if I remember right. Pretty rare though.

They did also make a specific two tone generator box for ssb. They did have a pretty good sine wave out. You probably won't see many around though.

Have you checked the RF power from your quadrature driver with resistive
loads? It can be very misleading if you measure it whilst connected to the
mixers.

I have an Alinco DR590. I replaced the battery in it. I can turn it off and back on and it stays on the channel I left it on. If I turn it off and leave it off for an hour or so it always goes back to 145.000 and 445.000.

It is constantly hooked up to my 12 volt battery.

What could htis be?

Thanks for your reply,

I have checked the output power (voltage) from my quadrature driver
with a 50 Ohm load. The output voltage dropped by a factor 2,
indicating a good match. The same happened when I attached the
mixers (SBL-1) instead. I assumed that the LO-input resistance of an
SBL-1 at 7 MHz is close to 50 Ohm and purely resistive.

If there is not a plausible explanation for my results I will redo
the measurements, to exclude measuring errors.

Paul, I don't want to sound critical here, but this newsgroup is
about "homebrew." In that light, I'd suggest a simple quad
op-amp circuited as two phase-shift oscillators (pick the AF
desired) out of two of the op-amps in the quad package, use
the third as a resistive summing mixer. The summing mixer
will have a low output impedance capable of driving anything
from low-Z to high-Z. Almost any quad op-amp IC will work
if their open-loop frequency response unity gain is at least
1 MHz (which is to say just about all of them). Use whatever
DC supply is handy (within the op-amp supply ranges).

The fourth op-amp in the package is either spare or can be
made into a preamp with its output mixing in the summing
mixer. Basic op-amp circuits and how to calculate them
are mature subjects and found in many texts and on the
Internet.

I doubt there is a "typical" DVM (of the handheld variety)
that cannot reach into AF with calibration, made anywhere.
Checking the DVM specs is a must if it is unknown. Even
the ultra-cheap oscilloscopes have response beyond AF.
[I had one of the original Heathkit model O-1 'scopes
made from a kit a half century ago, reached 50 KHz+
before rolling off 3 db in response...gave it away a decade
ago... :-)]

"Hard to get a calibrated output?" I'll disagree if using the simple single-IC generator I've described in general. A phase-shift oscillator uses an R-C network which can be configured as a low-pass filter (R in series, C in shunt). Many textbooks have easy formulas for parts values. The AF R-C filter loss is a known quantity at 180 degree phase shift for oscillatory feedback...combine that with an op-amp gain set by resistor feedback (the DVM can check the resistance values rather accurately) and the output sine voltage will be constant. The summing mixer output can have a gain of unity if desired, or any value needed. The output into a microphone input can be done with a one- or two-stage resistive voltage divider (depending on parts values available). The ohmmeter part of a DVM can check the resistor values and the level into the microphone input can be calculated on paper.

No computer with sound card needed. Just a little perf-board assembly (if quick assembly desired), may be battery powered or by a cheap series regulator IC from a cheap wall-wart. The op-amps insure low distortion at AF from all the negative feedback setting the closed-loop gains low. Output AF voltage stability will be good if the DC supply is stable.

For those that don't want to go through the hassle of calculating anything, use a DTMF assembly from a junked telephone (of the North American variety, haven't checked other world regions). They automatically generate two simultaneous audio tones out of a choice of 8 frequencies; four frequencies in a "low band," four in a "high band" the "bands" on either side of about 1 KHz.

If I remember correctly from a project of three decades ago, the Bell System specifications required a fairly pure sine for each of the tones selected. Don't have the specs now. As I recall, the early Western Electric telephone sets used only two transistors for DTMF generation so a homebuilt two-tone generator is NOT difficult to make from scratch.

I can't imagine what they want a two tone signal for in alignment.
Maybe to set the alc level?

To do much else with it you also need a spectrum analyzer.

Did I miss something or are you suggesting using a Wien bridge circuit as an audio oscillator ? How should the amplitude be stabilised in order to get nearly a sine wave output ?

While I guess that quite a few radio amateurs with professional background in electronics are following this newsgroup, do not forget that most young radio amateurs (with limited test equipments) are much more used to playing with computer programming and computer hardware than working with circuit design.

Both the traditional approach as well as some more day to day approach is required, in order to make amateur radio a viable hobby even in the future.

Diode mixers make a real mess of the input LO signal, if you look at what
happens to it with a 'scope. They have to be fed from a 50 ohm resistive
source, but they are not really resistive themselves.

1230. SSB demodulator

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-02-23 10:27:53 UTC
From: mrkrishnan@gmail.com
Message-ID: <1109154473.078854.291410@g14g2000cwa.googlegroups.com>
Source record: 20161

Hello,

I am trying to implement an SSB phasing receiver using the GNU Radio
toolkit [1]. I do not have an RF frontend yet, so I had to depend on
those fortunate folks who had the required hardware to get some real
world samples. They samples are captured as given below:

```
50.25 mhz
cos
---- x ------- I
|
|
fc=50.30Mhz ADC ->
|
|
---- x ------- Q
sin
50.25 mhz
```

The LSB signal which was transmitted at 50.30 mhz is digitally
downconverted with an IF of 50.25mhz. The complex samples I have is
centered at 50 khz. Now
I do exactly as described in the KK7B article on phasing receiver[2].
The I and Q signals are downconverted to baseband, and lowpass
filtered. The I channel is delayed and Q channel is passed thru hilbert
filter.

I get the audio output, when the I and Q are subtracted. Fine. But I
get audio even when they are summed together!!! i.e There is no
sideband suppression. I am wondering what the problem is. I looked at
the hilbert transformer freq response. It looks okay (allpass, with
nulls at zero and fs/2), could this null at zero cause a problem,
because the input is already at baseband?

Any advise/help will be greatly appreciated.

Thanks
Ramakrishnan

No, just let them catch up on maintenance that gets pushed aside, or
let them go to work for the cable company! :) They are still doing
repairs in Ocala from last year's hurricanes and its almost time for
hurricane season again. I saw some wires still on the ground along I-75
near Gainsville a couple weeks ago that went down during Frances.
Progress energy just repaired a damaged pole near my house that was
damaged during Frances.

There is no sideband suppression with I/Q demodulation until you get your carrier synchronized to the transmitter's carrier. If there's no mechanism for doing this, you don't get sideband suppresion through I/Q demodulation. (Well, you may experience rapid fading if you're within a few Hz, but I don't think you want that!)

There are some homebrewers who do not-completely-suppressed carrier with synchronous detection. It's sort of SSB but not traditional ham radio SSB. In traditional ham radio SSB you try to suppress as much of the carrier as you can, and this won't help you synchronously demodulate it.

Without that synchronization, just use a bandpass (IF+300 Hz to IF+3000 Hz for example for USB).

Tim.

yes they do. I've also used square wave drive and found that you have
to be sure your really driving them with 7-10DBM. A 74F74 really
can't do that though it looks that way. I found I had to use a
parallel group of 74HCT244 buffers (minimum of three) to get good
drive.

But he's not talking about synchronized demodulation, he's talking about
SSB demodulation.

Phasing demodulation was around before "synchronous detection" was described
in CQ in the late fifties. Where the carrier comes from is irrelevant, it's
about the proper combination of phase shifts to select which sideband
is being received. Add the outputs, and you get one sideband, subtract
them and you get the other.

Synchronous detection merely adds a means of locking the locally generated
"carrier" to the incoming signal. And of course, one can have sync
detection without selectable sideband.

But he's talking about SSB, and there's neither a carrier, nor two
sidebands to sync to.

But if he is doing this right, he should not receive the incoming sideband
if he has the combinations set up for receiving the other sideband.

I have no idea what's wrong, but this has nothing to do with synchronous
detection.

I suppose what the OP needs is the square wave equivalent of a +7 dBm sine
wave. I'm not sure what that is.

Here's my guess: it's a standard, which would be available in almost
any professional radio test lab.

Hence, it may simply be a convenient signal to use when performing
ALC and audio-pathway calibrations.

As is sometimes said, "The best thing about a standard is, sometimes,
that it's a standard. If it happens to be a _good_ standard, so much
the better!"

To answer my own post: I think it should be 1V p-p for the equivalent square
wave, which is the same power as a 0.5V rms sine wave into 50 ohms (+7 dBm).

I got the impression he was using an I-Q system to implment a hilbert
transform. The result is an image suppressing system that can
demodulate SSB with a baseband IF.

Essentually what a KK7B R2/miniR2/R2pro(RX) and the companion T2
(transmit) using aboth a 90degree I-Q RF path and an +45 and -45
degree audio processing path.

As someone running a 6m analog phasing rig what your describing makes
little sense to me.

Will not work unless you down covert again to baseband.

The signal you should be looking at is SSB rf source at 50.250 with
a 90 degree I-Q local osc at 50.250 and an audio baseband. Then
sample at greater than 20Ks/S with two channels and process them by
placeing phase delay of 90 degrees on one path and the and summing
them.

Unless your considering baseband signal desired to be the 50khz signal
then what you've done is created an image reject mixer with a 50khz
output and not an SSB detector. The image reject mixer case means
your signal is in the output passband at LO+ 50khz but not at
LO-50khz. You'd still have to repeat the process again to get from
50khz to recovered audio with a 50khz digitally derived LO and mixing
process. You can do that. In the end your doing something that
needs only to be done once. Look at EMDRF [Experimental Methods in RF
design] doing SSB in DSP is coverd there.

I suggested an R-C Phase Shift oscillator. With a resistor
feedback to set the gain of the op-amp to just overcome the
loss in the R-C network (3 caps, same value; 3 resistors,
same value) feeding back to itself. It isn't much used but it
has appeared in nearly all textbooks I've got. With stable
supply voltages, the sinewave output will be fairly pure and
reasonably constant in amplitude.

Well that may be, but consider that a personal computer
CANNOT build all of the simple sources (and attenuator)
necessary for a two-tone IMD test of a transmitter.

Don't get me wrong on computers. I think they are one
of the miracles of technology of the last millennium. I've
written my own circuit analysis program(s) and wrote a
filter component synthesis (and response analysis)
program on my PC and have used them extensively. They
are excellent in SIMULATING a given circuit (with the
proper modeling). Computers cannot build a circuit and
sometimes need extra, out-board circuits to function in
a particular application (a 40 db attenuator for example).

A single DVM and a hot soldering iron are basic tools
for any hobby electronics workshop, but they have
limitations on what they can do. If I wanted a "first
look" on the purity of a sinewave, I'd check it with an
oscilloscope first. A DVM would read the average (or
whatever) amplitude, depending on its AC limitations,

but that's about the limit. A simple oscilloscope doesn't cost the same as a couple of mortgage payments but it WILL show the purity of a generated sinewave, something necessary to prove that an IMD two-tone test source IS good enough for test purposes. There are limitations on what a particular hobby workshop can do; sometimes what one wants to do conflicts with what must be there to accomplish something. That alone will determine what "the future" planning must be.

>Both the traditional approach as well as some more day to day approach
>is required, in order to make amateur radio a viable hobby even in the
>future.

I don't know what the "traditional approach" is in regards to a hobby activity (homebrewing IS a hobby activity). I've been a hobbyist in various electronics since 1947, a computer programming hobbyist since 1976. Doing some things requires more workshop equipment than a DVM and a hot soldering iron. Doing some things requires self-education into the whichness of the what in circuitry in order to accomplish something. That's just the way things are in a technologically oriented hobby...like amateur radio activity beyond just using radio equipment to talk to people far away.

Thanks for the ideas. I will try to acquire EMFRD and look for more
details.

I am not having an RF frontend, the samples I have are in a file
captured by someone else and they are centered around 50 khz. I am
doing the mixing again to baseband, so yes, I am unnecessarily doing it
twice instead of once, but since I have no access to hardware now, I
have no other option. I will verify the waveforms at various points
again and get back.

Thanks again for the helpful comments. It was a bit confusing for me
initially to work with the complex digitally downconverted samples. I
think a bit of confusion still persists. I will go through the whole
thing again.

Thanks
Ramakrishnan

I don't think it is, the average value (same as RMS) will be 0.5V, which is
+7 dBm.

What is the maximum
> power a SBL-1 mixer will survive?

I think it will take +13 dBm, performance will suffer if it is overdriven.

Keepthis in mind:
+7dbm (the recommended RMS input for a level 7 mixer) is about 1.5Vpp sine. This holds up to reason, as a DBM has two diode-drops that the LO must overcome in order to switch the diodes properly. Therefore, if you use a square wave, you also need to supply about 1.5Vpp, or the diodes won't switch.

There are two common misconceptions many people hold about these devices. One is that they are inherently 50 ohm devices. In reality you will only see 50 ohms on a given port if the other two ports are also terminated in 50 ohms. You could run the device just as well at 75 ohms if you keep it balanced properly. Also, many people think that the LO input is power dependent. This only partially true. It's really voltage dependent, requiring sufficient drive voltage to turn on the diodes and pump an amount of current through them that is large compared to the expected input RF signal.

There is no magic in these things. They're just diode DPDT switches that reverse the polarity of the RF signal at a rate determined by the LO frequency. This is essentially the same as multiplying the RF signal by +/-1 at the LO rate. Simple math shows that this multiplication process yields the sum and difference frequency products. The more symmetrical the LO switching waveform, the more perfect the multiplication. This is why square wave LO drive is preferred.

Thank you. I've worked with them for years and the number of myths
are amazing. An SBL-1 is an amazingly rugged device and +13Dbm
is not a problem.

One problem with using digital logic, especially ttl to drive them is
that TTL is a current and voltage limited output with a variable
output impedence. A logic low can sink more current that a logic high
can source and that means significant non-linear behavour.
Also bipolar TTL logic high is not 5V, typically is around 3.2-3.5V at
rated current load and worse at higher currrent. When you drive a
DBM with it that tends to show as degraded signals, spurs, level
problems. When I drive a DBM with logic I use CMOS drivers as they
offer near symetrical drive for both levels and better overall output
voltage. So it's important to know the driver can supply the current

(about 30ma P-P) and the average 74F74 can do that only marginally and if there is any attenuation between the '74 and the DBM it's not going to work. Buffer it with a 74CH244 (octal buffer) with 4 buffers in parallel and you can easily push the 60maP-P at 5VP-P and allow for a 50ohm 5db attenuator for a more correct level. However, pay attention to grounding and bypassing the CMOS under those uses they can send annoying high current spikes into the power sources.

I can get down to 0.01% THD with 4th order active filtering of a square wave -- as measured on an HP339 THD analyzer. For the fellow who had asked the original question I suggested the switched cap filter -- but there is always going to be some noise clocking through. Using the interactive filter software on Analog Devices or Texas Instruments website is pretty easy, but necessitates more parts.

Sorry not to have included "odd harmonics" but I guess you know what I meant.

Thank you all for your help, suggestions and especially for the simple explanation that the mixer diode pairs need enough voltage for switching. I will remeasure with higher voltages and use buffers that supply enough current to drive the mixer.

Hi Roy,

I made no assumptions about the atmosphere, neither loss, nor noise.

I did assume that my antenna is about 0 dB gain and I further assumed about 10 dB loss for the temporary wire running through the wall of my house to the antenna (just a simple piece of wire running up a maple tree). I thought the 10 dB would be generous.

I assumed that the antenna of the person receiving was also 0 dB and I assumed that his receiver would have a sensitivity of about -80 dBm. I think that's pretty conservative. I would guess that modern receivers go well under -100 dBm for sensitivity; especially for CW operation.

As I said, I assumed nothing about atmospheric loss. I'm not quite sure what atmospheric "noise" is. Where does that come from? Is it what you call atmospheric loss, or is it something else? In any event, I would consider that to be a "receive end" problem.

I got a not from someone who worked a 500 mile contact with another QRP crazy who was using 50 micro (not milli, micro) watts. That's amazing. It gives me hope that I'll get my first contact soon.

Thanks for the reply.

There's a Real Cult of QRPp'ers - extra, extra low power ops - that try
to achieve ever higher and higher "Millions of Miles per Watt" numbers.
(Of course, BPL will kill them if it rolls out.)
Just imagine _accurately_ measuring power out at the microWatt levels!

This ol' hobby has a lot of interesting nooks and crannies.

gl with your project.

Hello Pete .....I worked a fellow on my SMT with 360 mw who was using 16 mw from his car using a hamstick. He was from the Annapolis MD area and I am from nr Pittsburgh. The thing that got me was that he was using a 40 meter Hamstick. Therefore the antenna efficiency at this freq. would be, to say the least, ..marginal. I don't remember the call or report as it is in my logs in storage somewhere. I will be retrieving them when the new radio room goes into operation hopefully in a few months. Give me an e-mail Pete if you want to try a sked one night ...nothing ventured nothing gained ....

You don't have an 80 meter parabolic dish in your back yard? (aimed
horizontally . . .)

Maybe with a power line running the 40 miles and some filters . . .

==========

I once worked 10 miles on CW, with 10 milliwatts on 160 meters, in daylight with my 20 feet long antenna lying on the ground, and a local noise level of S6. The other fellow had a half-wave dipole running 40 watts. He copied me OK.

Propagation must have been by groundwave (on account of time of day) partly over densely populated industrial areas and partly farm land.

But to translate from this information the possibility of acheiving 40 miles on 80 meters with 7 miliwatts requires some extra information from your end.

It's best to begin calculation with some sort of standard - some facts which you already know by experiment or hearsay and can reasonably be depended upon.

Suppose it is already known that with 100 watts on 80 meters, between two not necessarily identical antennas, of unequal efficiencies, with a radio path length of 100 miles, gives an S-meter reading of S-9 + 12 dB at one end of the path.

At 6dB per S-unit, this reading is 2 S-units greater than S-9. If you like, call it S-11.

Suppose the power of the transmitter at the other end goes QRP and is turned down to 10 milliwatts. This is 1/10,000 of the original power, or 40dB down, or 40/6 = 6.7 S-units smaller in received signal strength.

S-11 minus S-6.7 = S-4.3

So provided the noise level is less than about S-4, the 10 milliwatt transmission will be fairly easily copied at a distance of 100 miles. Which is now not so ridiculous as it may first sound without some thought being given to it.

Anyone know where I can see a schematic of a common emitter power supply? I've always read about using the emitter of a pass transistor as the positive terminal output (Common collector). Taking apart this trip lite power supply I see that they have the negative terminal connecting to the collector of the npn pass transistors. This seems like it would extremely complicate the regulation design. Can anyone explain the benefits, and where I can learn more about this design technique?

Actually, I'd rate the handbook as less and less about useful projects.
I'd recommend everyone have one, at least one, but it seems less about
building these days. I'm not sure if it's because they are including
fewer construction pieces, or if the theory has gotten larger so it
dwarfs the projects.

The ARRL has books that are much more about construction articles,
as they've always had. They used to have a slew of books about
specific categories (ssb, mobile, VHF, etc), that were only reprints
of QST articles, and the focus was on building. They phased those
out years ago, but in recent years they've come back. Things like
W1FB's "Notebooks", and "QRP Power", little of it is theory so
rather than selecting one sample of a transmitter and a receiver, etc,
you get pages of it. If you don't have a good selection of QSTs,
then these books are a great source, and they've kept relatively low
prices compared to the Handbook. (I paid $4.50 for my first Handbook,
back in 1971, and all the other ARRL books were the same or less. The
Handbook has ballooned to fifty dollars or so (at least here in Canada),
but you can get many of the other ARRL books for ten or twenty dollars.)

I finally got a copy of the relatively new ARRL book, "Experimental Methods
in RF Design" in December, and it is so much more filling than the last
Handbook I bought, a few years back. Just as "SOlid State Design for
the Radio Amateur" from 1977, the focus is on building, but also about
topics that often aren't covered in the Handbook.

It sounds like a standard constant current supply circuit - the collector
current is fairly constant with a varying load if the base is held at a
fixed voltage.

Yes, this is correct; the problem is that close to the 500MHz split, the filters combine together so as to create several resonances. I'll try the T combiner approach; this should tend to 'de-Q' the resonances.

An isolator (or circulator) would work here, but I'm not aware of any that cover such a wide bandwidth.

The suggestions for 'quarter wavelength' anythings aren't appropriate given the wide bandwidth.

Thanks for all the help,
---Joel Kolstad

With the NPN collector as the negative output terminal, which is
usually also connected the chassis ground, you can install the TO-3
transistors directly to the chassis without insulation :-).

Seriously, the standard emitter follower configuration requires quite
a lot of base current, especially if bad transistors, such as 2N3055
are used. These have a low current gain and high Vbe even at moderate
currents. Now the question is, where does this current come from ? In
high current supplies there are usually an other emitter follower
driving the series pass transistors and this driver has also a Vbe
drop. Thus, even higher voltages are needed to drive the base current
into the driver.

The regulator needs to operate quite a few voltages higher than the
final output voltage. In addition some extra margin is needed to allow
for the voltage drop during capacitor discharging. If you take the
regulator voltage from the same capacitors as the series pass
transistor, the capacitor voltage may have to be 5-10 V higher than
the output voltage. This excessive voltage needs to be dissipated in
the series pass transistors at high currents, creating a lot of heat.

One way to avoid this, is to use a separate medium current secondary
winding to drive the regulator at a higher voltage and use a slightly
lower voltage, high current secondary winding.

To avoid this a PNP transistor is used on the positive side or a NPN
on the negative side. It may be easier to look at the situation with a
PNP in the positive side.

In this circuit, the current needed by the regulator flows from the
positive capacitor end through the emitter and out from the base
through the regulator to the negative end of the capacitor. Now the
regulator voltage is below both the output voltage and the capacitor
voltage and the emitter needs to be only about 1-2 V above the output
voltage. You can even drive the series pass transistor into saturation

(which requires quite a lot of base current) and hence reduce the capacitor-output voltage difference even further, since it is now easy to sink the base current.

This is how the LDO (Low Drop Out voltage) regulators are implemented.

They interviewed one of the spammers on local TV just before
Hurricane Frances went through. She was bragging about how easy it was
to opt out but couldn't see what was wrong with getting plastered with
her crap in the first place.

The bandwidth problem here is getting worse. If you don't go
broadband you might as well give up accessing the net until midnight.
Also, newer web design software is so bloated some servers crawl to the
point they don't have the capacity or bandwidth to do their job.

Hello all,

Im looking for the datasheet of an Avantek YIG tuned oscillator ,
namely part number (stamped on it):

Model: Y084-1679
Freq: 1-404672/B

so I can use it whithout fear of destroying it.

Thank you , Dan

IMHO not, (practically maximum about 10x less probably with good
simple antennas & RX-ver & not too much noise & disturbances & w/o big
obstacles & using narrowBand CW modulation for solid reception of
direct surface wave ...

http://www.radioinnovation.com/Howto/how_far.htm

if your Qrp TX puts to antenna 7mW /0.6Vrms-50ohm/ & an average RX has
sensitivity around 0.6microVolts/50ohm, there is difference in
voltages about 1 million times (120db) !

for a 40 mile distance you would need approx. a 1/2W TX or even more
IMHO @ your 3,75MHz TX! you can gain something with both side very
good antennas ...

I am not really an expert in the matter, but I was also searching for
years for some kind of "idiot proof" but simple (not complicated math)
formula for receiving range but for higher frequencies like 40MHz or
so .. Since the recieving of a signal is proportional with voltages on
antenna (& reverse proportional to rise of frequencies) I time ago
derived/simplified a lot the math formula (confirmed myself by some
experiments I made).

you need on TX antenna /Vrms=Eff@50ohm/ minimum:

50mV/1km/1MHz [simpliest as possible formula!] for 1/4 wavelenght
or such/similar gain antennas.

that means in your case 0,19V/1km (@3,75MHz) & since you have 0,6Vrms
on TX output means that can you reach normally 3-4km (2-3 miles!)

But I could be also wrong ... :-)

To enhance reception double the TX output voltage/power or make more
efficient antennas. Thats easier with higher frequencies to make high
gain ones & not to be really monster big on big towers ...

PS.: another simplified answer derived from above simplified formula:
your 7mw TX has a range (@80m wavelenght) for about 40x the wavelenght
receipt with an ordinary common RX .. :-) ....

hope it was enough simple explanation ...

The current record on 80 meters is 546.8 miles with 0.0406 mW. By comparison, your transmitter is QRO. Of course, that was with good antennas. The transmitter was an off-center fed dipole, the receiver a 1000 ft. beverage.

80 meters is a pretty QRP-unfriendly band. But on a cold winter night when the sun is behaving, it can be pretty good.

You might want to rummage around on the archives of QRP-L
http://mailman.qth.net/pipermail/qrp-l/
There are a fair number of folks fooling with this kind of setup.

..

Hi Brian,
What you can use is low-side injection at 36.7125MHz.
Normally, high-side injection is used since it has fewer in-band spurs. A freeware program such as AppCad will generate spur charts for you, and you can see what happens. Because you are only interested in one frequency, it is pretty unlikely that you will have any problems.
The circuit topology can be like this: your I.F. output will feed into the RF port of the NE602 mixer. Because this mixer has an IP3 of only -10dBm or so, your 1dB compression point will be at around -24dBm. Your RF level should be at least 10dB below that point.....-40dBm is a good figure to shoot for. This corresponds to a 2.24mV level into 50 ohms. It is a good idea to have a "pi" type of resistive attenuator ahead of that NE602.....this way, you can adjust the input level as needed. The 50 ohm figure is good to shoot for, but there are always imaginary terms (reactance) at the mixer input so calculations are only a starting point.
You can use the on-board oscillator of the NE602 for you LO. A 3rd overtone crystal would do the trick. You can actually use a Colpitts scheme, adjusting the feedback capacitor values so that they have a high reactance at the fundamental frequency of the crystal; this way, only the harmonic will be generated. Over the years, I would use a 4:1 ratio of the top cap vs the grounded cap. An example is 120 over 30pF for a 10.7MHz oscillator, but your mileage may vary.
Your I.F. output really should go through some type of 21.4MHz tuned filter, because you are going to have two sidebands coming out of that mixer. The lower sideband (the desired one) will be a 21.4MHz, while the upper sideband (the image) will be at 94.82MHz. You don't want to have this response.
Since the NE602 has a good NF and has gain, you shouldn't need a buffer amp, unless the WJ unit presents a 50 ohm load. You need to know what level the WJ unit requires, so that you can provide the proper level from your translater.
I hope this helps.

Pete

Pete ... thanks for the help!

I am planning to build a similar mixer to allow use of my Kenwood SM-220 / BP-8 panadapter (I think those are the model numbers) with my FT-1000D.

I will keep your suggestions in mind!

I wonder if someone hasn't already done this ????

Thanks Pete. Would it be possible to fabricate the design in such a way as
to acomodate differant IFs. Maybe some type of switchable or multiport setup
so it can be used on differant receivers?

You could so a universal PC board layout, as long as you use the same form factor for the components of the different iterations. To have a "bandswitched" unit isn't a trivial factor. You would need relays, PIN diodes, or RF switches to switch in the different crystals, I/O filters, etc. Don't forget that you would also need an adjustable attenuator for the different receivers' I.F. outputs, and maybe, different gain in the output stage of your translator. The LO crystal's feedback components probably would also have to be changed in value. You would be better off doing a board layout and building the different versions as you need them. Another thing to consider.....does your receiver already have a bufferred I.F. output? You need that, so that you don't load the crystal filter of your receiver, thereby changing its response.

The main problem is the morons that comprise the 4 percent that actually
buy crap from the spammers.

FOUR PERCENT! That's a phenomenal return, even for a pre-qualified
mailing list.

As long as they can keep getting paid, they'll keep doing it. It's like
the war on drugs - it's like stopping the tide.

Sigh.
Rich

> KB1LZH
>

Guys,

With this post, I have received several useful suggestions and comments. Thank you very much.

Many of you are curious about the assumptions I made when I made my calculation of 40 miles. I simply went with something I know: the radar equation. I made a simple adaptation to the radar equation.

It starts with a simple premise that the power in my transmitter will be radiated equally in all directions. That is equivalent to a zero DB gain antenna. I assumed that the receiver will have a sensitivity of -80 dBm. I then, simply applied the basic fact that power diminishes as the square of the range. That leaves a power density at any given range of P divided by 4 pie R*2. (Forgive the lack of an equation editor)

The next assumption involved the capture area of the receiving antenna. In radar, the capture area of an antenna is proportional to the wavelength squared. With a zero DB receiving antenna, the capture area would be simply lambda squared divided by four pie.

With those simple assumptions you can determine the amount of power available for a receiver. Since my little transmitter is a simple breadboard with three transistors and a wire that runs out of my house and up a maple tree, I made a further assumption that I have about 10 DB of loss delivering my transmitter power to the antenna.

That 10 DB loss along with the assumption of only minus 80 dBm sensitivity in the receiver seemed pretty conservative to me. Most receivers can probably do much better, especially with CW operation.

Of course, as RegEdwards has pointed out, what is really needed is a good benchmark. Several of you provided me with some interesting benchmarks. Thank you very much for your replies.

Regards,
Peter Barbella

God gave us brains to determine when religion is a virus, and when
it is good for our spiritual live.
>
> You just got to love a god that turns people to pillars of salt,
> and commands fathers to kill sons just to test faith.
Shut off your brain and follow, that's what the devil wants.
Drugs alcohol etc. wil help you with that, put a label on it, in name
off God.
I'am just smarter than that.
>
> I MEAN YOU JUST GOT TO LOVE THAT GOD!!!! DAMMIT, HE COMMANDS YOU!!!!
No one commands us ! we may believe in Him.
It's our choice.
You also have to understand "the bible of the devil".
THEN you are able to see when something is right or wrong.

>I made a choice to just be a decent fellow.
Thats positive, stands for live, in harmony with nature.
Nature created by God.
Brains give us the opportunity to have a choice !
Also a gift of God, it's part of our being.
You can use words right or wrong.
For live, or against it.
We need brains to interpret words.

Or follow your hart, when your a good man.
Its just like Abraham Lincoln said:
When I do wrong, I feel bad.
When I do right, I feel good.

The power of words!
You can make tools out of steel, or make guns
from it to end lives.
You are responsable for yourself ! NOT God.
You make choices.
He gave everyone a tiny piece of Himself, the spark
of live.
It's up to us to use it or not, that's His message.

There are so many ways to interpret His Word !
You must read it with a positive attitude, otherwise
it becomes a word of the devil. (negative, against live)

If you have trouble with that, let speak your hart, you did !

Just what I was going to suggest the O/P do. Apart from the earthing the neg
terminal, using a PNP pass as an afterburner makes a helluva lot of sense. I
did that on my very first home-made bench PSU where a 723 drives the external

PNP (darlington) to >15A. I chose this configuration because the available transformer didn't provide enough headroom for cascaded emitter followers.

(and I absolutely HATE 2N3055's with a passion, for the reasons you state - low HFE at any sort of current worth having).

Look at data sheets for typical integrated regulators and they usually have sections on external pass transistors for boosted current capability. Most often these show both an NPN emitter follower and a PNP arrangement. Your unit sounds like the PNP configuration inverted.

with just probably 40mW IMHO (not 40 microW)

Incredible distance, must had ben hell of a reciever & antennas &
probably a reflected wave ... wow if this is true .. even for very
narrowBand non-modulated carrier CW

BTW, that my simplified formula I calculated for Phono work, with CW
the distances achieved normally I know are few times greater ...

Maybe there should be a law against buying things from spammers.

And a law against knowingly providing credit card, banking, or Internet (web hosting, email) services to spammers.

Especially the last of these.

Unless you have an incredibly poor antenna or an incredibly poor receiver, you'll never hear the receiver noise on 80 meters because the atmospheric noise is much greater. There are a number of sources of this noise, man-made and natural, and its level varies a great deal. It's not the same as loss, and although it's a "receive end" problem as you say, it's nothing you can improve by altering the receiver. There's just a little about it in the ARRL Handbook, but I'm sure a web search will reveal a great deal of additional information.

Apparently you assumed that the atmospheric noise is zero. That's not a valid assumption at HF.

I still wouldn't be surprised at a 40 mile contact with 7 mW however.

-NOTICE-

The "PileupBuster.com" domain name is For Sale.

For less then the price of an HF rig you can own the ultimate Ham Radio domain name.

The PileupBuster.com domain has immediate name recognition to everyone associated with Ham Radio. Plus, the sales and marketing potential of this name is unlimited.

The minimum offer on this domain is $1,250.00 (US Dollars). The PileupBuster.com domain name will be sold to the person, company or group that makes the highest offer. International offers are welcome.

This is a Private Auction. No one will see what you offer and you will not be able to see what others are offering.

You may begin submitting your offers on Saturday February 26. No offers will be accepted after 12:00 midnight (Pacific Time) on Friday March 4, 2005.

TO MAKE AN OFFER, GO TO: http://PileupBuster.com When the web page comes up, look right under the PileupBuster.com name. You will see "This domain is For Sale" then click on: "More detailsï¿½" You will then see a box to enter your offer. Enter your offer and then click "Make Offer"

This sale is supervised and regulated by SEDO (sedo.com), a highly respected International domain sales company.

If you have any questions, please feel free to contact me at: erfurth@gmail.com

Good luck.

73s,

Bill

> I need to replace the MODE switch on my TS520.
> It is a rotary wafer switch.
> Can anyone help?
==========
Perhaps you can specify the switch :
1)number of switch positions and the total angle the switch shaft makes.
2)number of switch functions ,identifying the number of separate switches
inside the wafer or wafers.
3)outer diameter
4)depth dimension of the wafer (pack)
5)shaft diameter and the diameter of the screwed thread fixing the switch to
a panel.

The TS-520 is not a recent transceiver ,hence the switch might not be all
that exotic.

If I have a suitable switch in my junk box ,I'll be happy to send it to you
foc.
I understand you are in the UK.

Yeah, 40 microwatts, really.

I probably should hasten to add that this was not a random QSO. The transmitting station has been sending a beacon at various times, frequencies, and power levels for several weeks. There have probably been several hundred stations listening for that beacon. While this particular one was the best on 80 meters, it really isn't all that much of an outlier. Plenty of other stations were in the same general neighborhood on other nights.

It did surprise me to see this on 80, though. As Roy points out, the absence of atmospheric noise is not a valid assumption on HF, and noise does increase with decreasing frequency. This is exactly the opposite to your radar experience where it is all about receivernoise. Even at 10 MHz, the most basic receiver will be sufficiently sensitive that it is limited by atmospheric noise. This seems to be a particularly bad winter for noise on 80, although there have been occasional evenings when the conditions have been pretty astonishing.

Also, the noise causes in the lower HF region tend to be somewhat different than those in the upper HF. Paul Harden made a couple of nice postings to QRP-L explaining some of that after that quasar whacked us back in December I think it was. Interesting to note that the news media only picked up on that event last week. Pretty astonishing, though, that something millions of light years away could be so energetic as to shut down 80 meters for a couple of days!

By the way, I see that Paul will be speaking at Dayton (FDIM) this year. I was planning to go anyway, but it would be worth the trip just to hear him. This guy *really* understands what space weather does to our propagation.

However, the noise power is proportional to bandwidth, so if the
throughput rate is not defined, slow down the bit rate to reduce the
required receiver bandwidth, until the noise is weaker than the
signal. While the lower HF noise is not pure white noise, this
principle can still be applied.

For instance on the 135 kHz LF band, it is quite common to use QRSS
with a dot time of several seconds or even a minute and the reception
is done visually on the "Waterfall" (spectrogram) display. Although
the LF transmitter power might be several hundred watts, the
transmitter antenna efficiency is usually much worse than -30 dB, so
the radiated power is well below 1 Werp and the noise level is much
higher than on HF.

Theo -

OK. you have a Kenwood TS-520.

Do you have the TS-520 Service manual - that identifies all Kenwood parts by their original part numbers?

The TS-520 Service Manual (ZIP file of Adobe Acrobat) is a LARGE file available (download) from MODS DK
http://www.mods.dk/view.php?ListManuals=kenwood

Are you aware that about 86 parts for the TS-520 model are still available from Kenwood Parts? Many are switches - BUT you need to Kenwood part number for the specific bad Mode Switch wafer.

There already are, if not laws, at least terms of service that prohibit sending spam - in the US. They don't have any effect on the spammers in, say, Elbonia, however. This is why I'm in favor of some kind of central "spammer-list", where people can download the week's list of what IPs should be just dropped at the firewall. I have a "Blacklist" now that's 8585 entries long. Would you like me to post it?

I don't actually need it, though, since I don't go online with Windoze any more, and I don't answer spam. It's kinda weird, though, to get empty popups. ;-) (the sponsoring page can have a little popup script, that opens a second window, and tries to show a page from a blacklisted spammer.)

Thanks,
Rich

>several hundred stations listening for that beacon.

oh, that was the case ...

... well, I recalculated reached distance for usuable everydays
connection in real normal conditions with average equipment
/forgetting the extremes!/ (after some additional thinking reading
these posts) to even simplier formula than before & more realistic (a
bit larger distances reached) as follows:

to reach the distance of ONE full wavelenght (ex.80m for 3,75MHz) you
approx. need Rf RMS voltage on TX out for antenna (50ohm) :

1mV - for narrowBand unmod.carr.CW
3,16mV - for ordinary CW & SSB (+10dB)
10mV !! - for ordinary FM & AM or other (another +10dB = +20dB)
30mV - for PacketRadio - for no data loss (+ another 10dB)

... so original poster (Peter) could get out of his set normally 5Km
for sure (more than 3 miles with his 7mW-atts).

IMHO this is some kind of reasonable expectations about recieving
range ... bye .. :-)

1314. Jennings Radio Capacitors

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-02-26 22:37:49 UTC
From: Ed Bailen <n5kzw@arrl.net>
Message-ID: <8ut1215s3s18undbq6tgccaar1spq7205c@4ax.com>
Source record: 20147

My father-in-law, W9OIB (SK) gave me a couple of Jennings Radio vacuum capacitors several years ago. According to Google, they are 100 pf units. (They measure about 65 pf.)

Jennings Technology no longer makes these particular capacitors, and they never responded to an email I sent them a while back. Current Jennings Technology capacitors with similar dimensions (6.5"L x 2.5"D) are rated at 32 KV peak test voltage, 25 KV working voltage, and 87 A working current.

The devices are labeled "VCC-100 Jennings Radio" on the glass, and the copper electrodes are hand engraved "VCC-100 225-30" on one and "VCC-100 225-4" on the other.

I'm not going to use these and would like to put them up on eBay. To do that, I would want to be able to list their correct specifications. Can anyone on the group tell me what their specs are supposed to be?

Thanks,
Ed Bailen - N5KZW

The test circuit in the SA612 data sheet uses a 34MHz 3rd OT
oscillator. You should be able to tweak it to run at 28MHz.
The oscillator section appears to be a single NPN transistor.

Well, WTF? There's already a law against spamming, and it doesn't do
any good. Why would _you_ think your law would do any better????

> And a law against knowingly providing credit card, banking, or
Internet (web
> hosting, email) services to spammers.

> Especially the last of these.

Well, every ISP or ASP has a clause against spamming in their policy.
But the problem is they ignore it, and sign 'pink' contracts with
spammers. The worst offender by far is UUNet - part of MCI (was
Worldcom) See www.spamhaus.org.

One big problem is that no one wants to bite the hand that feeds them.
The UUNet system supplies connectivity to so many ISPs - it's
everywhere - that disabling it would put a serious dent in the
connectivity in the U.S. Like, 800 pound gorillas tend to get their
way, don'tcha know. :-O

Speaking of connectivity. Yesterday I was walking down the street and
noticed the manhole covers had the XO ground off, and replaced by Level
3. The FO companies spent zillions of dollars putting all that FO in
the ground, and they couldn't get enough of it leased to pay the loans.
So the only alternatives were either bankruptcy or merger. Perhaps this
is why the ISPs are too lenient on letting the spammers keep on
spamming. Money talks, and big money talks loudly. :-/

Wow. I just watched Sunday Morning (CBS). They had a piece on the guy
who invented the intermittent windshield wipers. Turned out he
eventually won $20 million from Chyrsler and $10 million from Ford for
stealing his idea, but ended up paying most of it to the lawyers. For
those who don't know, it's a SCR and a few other electronic parts that
trigger the W-W intermittently.

One thing is certain: the world would be _much_ better off if the LEAs
would enforce the existing laws. That sentence implies that they are

not being enforced at all. Well, we get an occasional sensational headline that says, "Spammer Convicted" (http://www.pcworld.com/news/article/0,aid,118493,00.asp). But they say there are only a couple hundred spammers that are reponsible for most of the spam; if the FTC would simply crack down on a few score, or even a few dozen, it would put a serious dent in the spam traffic. I'm not holding my breath, tho.

Someone should start a donation fund to pay for law enforcement personnel to track down, arrest and prosecute spammers. I heard that Microsoft and some other agency have a reward out for spammers. If people would just put up the money, the spammers could be decimated.

I average 6 spam E-mails per month, all of which are caught by my filtering and go straight to Trash.

All of them go to a specific publicly-known E-mail address which I'm about to replace with a form on my website.

Then I should be receiving zero.

C'mon, Jim. We all know that your son is doing that for you. ;-)

When you say form, what does that say? A specific error message that
refers to another email address?

On occasion I still troll the web for instances of my old email
addresses. I still find them from prehistoric times, back when I had
freebie educational email addresses. They just won't go away, and the
spammers still scrape them off the net, trying to sell millions of them
to other spammers. I was getting spam on my unix shell acct for a
decade, even tho the address hadn't been used for almost that long.

Hmmm. Did you also read about the "CAN-SPAM" law? (Link at the bottom
of the BP page).
http://www.angelfire.com/blues2/blowschunks/index.html

It seems Congress has not only de facto legalized spam, they're even
overriding states' rights by pre-empting state anti-spam laws!

There's a list of emails of congresscritters that voted for the law,
and they[0] recommend forwarding all of your spam to them[1].

Thanks!
Rich

Do you still have your grandmothers gold fillings for sale?

You might have better luck marketing "pile-a-shit.com".

Domain name resellers, lower than lawyers, you'll never see
skid marks in front of a domain reseller lying dead in the middle
of the road, just a line of 18 wheelers waiting to hit him a second
time to make sure he can't resell "deaddomainresellerintheroad.com"

Buzz off, go log into screwyourself.com You'll get instant recognition
there also!!!

I recently purchased an old crank-up motor driven 60 foot tower that I would hope someone could id for me. The motor belt drives a gearbox, which turns the cable pulley. It has a approximately 1 foot by 18 inch control box which has two high current relays and two glass contained relays. The glass-contained relays are in old 8 pin tube sockets.

The tower, itself, is in good shape. I would like to re-build the control circuits and out the tower in service. Any information anyone can give me on this tower will be greatly appreciated. See at www.winlyn.us/tower.jpg.

We'd like to invite you to join our free
WORLD SCIENCE e-newsletter, which
contains some of the world's most exciting
science news and photos long before they're
in the papers and magazines. A sample
newsletter is below.

To join, just send an email with "subscribe"
in the subject line to:
neutrino750 @ yahoo.com (remove the spaces).

The newsletter, sent out about every 3-10
days, contains short summaries of our new
stories, with links to web pages containing
the full stories. It's free: no pop-ups, passwords,
spam, or gimmicks -- that's our pledge! The full
story pages do contain small side ads (non
pop-up), which are what supports our news-
letter. YOU pay nothing ever. You can cancel
anytime simply by replying to a newsletter
email and typing "unsubscribe" in the subject
line.

Below is a sample newsletter. It doesn't
contain the full story links because we're not
allowed to provide them here, but the real
newsletter will contain working links.

****
LAST WEEK'S WORLD SCIENCE EMAIL
NEWSLETTER

* Possible dinosaur-bird missing link found:
It's not the first bird-like dinosaur ever found --
but it is the closest yet found to the actual
dinosaur ancestor of birds, researchers say.

Click here for full story (link will work in the real newsletter)

* Science in Images - A more life-friendly Mars:
Most Mars photos show a rocky, dry-looking land-
scape. This is another view: an area of the planet
that researchers think might have once been
habitable. They plan to explore further.

Click here for full story (link will work in the real newsletter)

* Another record: biggest blast ever in our
galaxy:
The most powerful explosion in our galaxy ever
recorded occurred recently when an exotic star's
magnetic field snapped, astronomers say.

Click here for full story (link will work in the real newsletter)

* New robots walk nearly like humans:
An older robot does it too, but it used 10 times as
much energy as humans do, researchers say; that is
changing.

Click here for full story (link will work in the real newsletter)

* Brain doesn't have universal language rules,
researchers claim:
Some researchers argue that language is more like
a creation of itself than a creation of our brains.

I can see you're another sheeple that hasn't learned to think for
himself.

Think about it: How can you 'legalize' something that had no prior
restrictions? Does what you said make any sense?

I agree that it was unwise to override some state laws, especially since
Calif had just toughened the spam laws. But don't try to tell us that
the law legalizes spam. The law puts restriction on spamming where
there were none before (nationally).

I don't know where you're at, but (the U.S.) congress had the foresight
to include a clause in the act that requires the Federal Trade
Commission to report back to congress in 18 months or so with how well
the law is working. If it finds that the law isn't effective, then it
can change the law, hopefully the worse for spammers. Perhaps when the
FTC reports it will tell congress that there is insufficient funding to
do the job. Then congress can put up some money and hope it helps.

But someday all the i's will get dotted and t's crossed and the spammers
will not have any way to hide. That may take IPV6, which seems like it
should have been implemented long ago, but still hasn't. Don't hold
your breath.

I've tracked down a summary of the alleged "anti-spam" law:
http://thomas.loc.gov/cgi-bin/cpquery/?&db_id=cp108&r_n=sr102.108&sel=TOC_0&
---excerpt---
Calendar No. 209
108TH CONGRESS
Report
SENATE
1st Session
108-102
--CAN-SPAM ACT OF 2003
JULY 16, 2003- Ordered to be printed
Mr. MCCAIN, from the Committee on Commerce, Science, and Transportation,
submitted the following
R E P O R T
[To accompany S. 877]
The Committee on Commerce, Science, and Transportation, to which was
referred the bill (S. 877) to regulate interstate commerce by imposing
limitations and penalties on the transmission of unsolicited commercial
electronic mail via the Internet, having considered the same, reports
favorably thereon with an amendment in the nature of a substitute and
recommends that the bill (as amended) do pass.

PURPOSE OF THE BILL

The purposes of this legislation are to: (i) prohibit senders of
electronic mail (e-mail) for primarily commercial advertisement or
promotional purposes from deceiving intended recipients or Internet
service providers as to the source or subject matter of their e-mail
messages; (ii) require such e-mail senders to give recipients an

opportunity to decline to receive future commercial e-mail from them and to honor such requests; (iii) require senders of unsolicited commercial e-mail (UCE) to also include a valid physical address in the e-mail message and a clear notice that the message is an advertisement or solicitation; and (iv) prohibit businesses from knowingly promoting, or permitting the promotion of, their trade or business through e-mail transmitted with false or misleading sender or routing information. ---end of excerpt---

Let's analyze this.
(i) prohibit senders of electronic mail (e-mail) for primarily commercial advertisement or promotional purposes from deceiving intended recipients or Internet service providers as to the source or subject matter of their e-mail messages

In other words, if you don't overtly lie about your product, you're OK, you can legally send all of the spam that you want to.

(ii) require such e-mail senders to give recipients an opportunity to decline to receive future commercial e-mail from them and to honor such requests;

Yeah, the ever-popular opt-out clause. This does a lot of good, at the bottom of megabytes of popups.

(iii) require senders of unsolicited commercial e-mail (UCE) to also include a valid physical address in the e-mail message and a clear notice that the message is an advertisement or solicitation;

Valid Physical Address. There's a vacant lot just down the street from me. Include a clear notice? How about not send it at all, huh?

and (iv) prohibit businesses from knowingly promoting, or permitting the promotion of, their trade or business through e-mail transmitted with false or misleading sender or routing information.

So, you can't use your anonymizer. Big deal. It still gets sent!

So I tend to agree with this guy:
http://www.angelfire.com/blues2/blowschunks/index.html

I believe I might start spamming with The Boulder Pledge.

Ah Seen Tha Light!

Thanks,
Rich

No, the problem is that it doesn't violate any fraud laws. They're not defrauding anybody. The problem is that they're loading up everybody's mailbox in the world with worthless spam email, the equivalent of ordinary junk snail mail. But with junk snail mail, at least you could use it for kindling. It doesn't matter that the content isn't deceptive - it's there, and it's jamming the internet. The only thing you could do is prohibit ISPs from allowing any spam to be sent through them, but as has been noted else-thread, they know which side their bread is margarined on.

Of course, a solution occurs to me, which would, of course, be even worse, and that would be to charge for bytes times # of recipients.

If you send an email with more than five recipients, it costs you a dime apiece for each additional recipient.

And you're not allowed to send any more than one email per, say, ten seconds.

But that will never be implemented. It makes entirely too much sense.

Thanks,
Rich

See my other post else-thread about my opinion of these alleged
"restrictions."

They only make it illegal to defraud, not to send out a hundred million
totally honest advertising spams. They don't care that there are
"restrictions" on "content" - it's still there clogging my inbox!

In a way, it's equivalent to commercials on free TV (and even cable, these
days). I pay for the use of the phone co's and the ISP's equipment and
bandwidth, and spam is just something I'm going to have to deal with as
it presents itself.

Hence, the blacklist.

And, who cares if it's up to date? Some IP numbers are blocked. Big deal.
If you want to take over the IP number of a known spammer who's been sent
out of business, you should be required to submit an approval form.
Otherwise, those IP numbers are blacklisted forever. Fuckem.

And, just because I'm a rebel, here's mine:
http://www.neodruid.net/LATEST_BLACKLIST

Thanks,
Rich

(yes, I own the domains neodruid.com, neodruid.net, and neodruid.org,
although neodruid.org is on the computer that I boot to Doze at least
once a day to do video games and porno, so won't always be available.)

"They" in this case meaning the gov't. That's all that's possible to restrict. If the restrictions were on honest spams, then the law would be declared unconstitutional because it restricts free speech.

> They don't care that there are

"They" in this case meaning spammers.

> In a way, it's equivalent to commercials on free TV (and even cable,
these

No, it's not! Commercials in the media pay their fair share to the media. Spammers, w/o permission, abuse services from the ISPs and our inboxes without paying their fair share. Spammers are thieves.

You can't legalize something that had no prior restrictions because it
was _already_ legal.

The spam is fraudulent when it uses spoofing to hide its origin.
Virtually all spam does so.

No, it's not equivalent. Junk mail is paid for by the advertiser.
Spammers pay nothing! They're thieves.

It depends on how you define 'legalize'. If no law applies to some activity, it could be taken as 'outside the scope of law', so when a law is applied to it, it becomes within the scope of law, and the verb 'legalize' could well be applied to that action of 'bringing within the scope of law'.

Hi, all concerned:

Is not the problem the avarice and greed of the daydream-believers and homecoming queens who've tried the mass-snailmailing GRQ schemes?

Forget the legislative approach. It only codifies that which moral, honest people are already doing. You obey speed limits on the highways, signal lane changes and turns, and declare _all_ your income, don't you?

Get an isp which allows multiple id's, accept the inconvenience of having to change your id fttt, and filter your email with a trainable $pamblocker.

The elephant has worse pests.

-------- Original Message --------
Subject: [Amps] FS:DENTRON CLIPPERTON V 2meter amp- JUNK!!!!!
Date: Sun, 27 Feb 2005 13:48:40 EST
From: JimMoci at aol dot com
To: amps@contesting.com

I have for sale a Dentron Clipperton V 2 meter amplifier rated @ 500 watts input with a 4CX250B. It is in pretty good cosmetic shape except for a small ding in the left corners. As far as working condition goes it does work but I think this amp is a piece of junk! (Hey I am honest) It has an LC tank circuit- it is not a stripline design like it probably should be @ 2 meters. It runs awfully hot and has a severly under sized blower. The tank circuit is under sized and runs very hot- so hot that it melted the solder running 200 watts FM. At 300 watts out it runs fine on SSB but I think it is still way to hot. These junkers are going for $600-700 on Ebay. Why? I dont know why but my guess would be a solid state 300watt amp is $700 and you still need an Astron RS70 to run it. I think it would be fine if someone installed a much larger blower but that would require hacking the cabinet which would ruin the collectability of the amp. At least it would be functional and reliable then. Better yet would be to convert it to stripline- there is enough room with some cabinet work and hacking. It would also be an excellent candidate for a six meter conversion where a conventional tank design is usable with a 4CX250B. I would like to sell this Denny Dentron junker -boatanchor for $550 to someone who can appreciate it for what it is!! :)
Thanks & 73, Jim W3ATV

Yes. And people will whine about the loss of their precious "electronic frontier" as the Internet ceases to be a fantasyland above and beyond the law.

The Internet was designed for use within research establishments where people were all, at some level, accountable and trustworthy. It has become a playground for con artists and pests.

It may take another half century. I'm reminded of the chaos that afflicted radio before WWI. People just chose their own frequencies and hoped nobody would interfere with them, knowingly or unknowingly.

(And thus I bring the subject matter back to that of the newsgroups we're in! :)

It is a good amp, if you use it to its rated output.
The 4cx250b is only rated for 250w plate output. Trying to get more from
that tube will shorten life, and produce much more heat.
I have used that amp running at 150w out and it just gets warm, and it
is solid performer.

There are those who feel that the CAN SPAM law both legitimizes and
legalizes spam, in two ways:

- It sets specific Federal boundaries on what sorts of spam are
illegal (and thus by implication states that spams which don't
cross those boundaries are legitimate), and

- It preempts most State laws which had stronger restrictions on
spamming, and therefore makes legal certain spams which were
previously forbidden by State law.

Are "overtone" crystals cut differently than "fundamental" crystals?
Or are they just specified differently?

In particular, say I took a garden-variety 20MHz fundamental
microprocessor crystal and instead used it at its fifth overtone,
trying to hit 100 MHz. The LC network is there to make sure that it's
on its fifth overtone. Will this "misuse" mean that the oscillator
will be harder to start up, less stable, more noisy, ???, than a
crystal oscillator made out of a real overtone crystal? I don't mind
if I "miss" 100 MHz by a several tens or hundreds of ppm, as long as
it's stable there.

If anyone knows of a place that ships off-the-shelf 100 MHz fifth or
seventh overtone crystals, I can avoid this whole exercise.... :-)

Tim.

Overtone crystal cuts are not fundamentally different from fundamental crystal cuts, so to a 1st-order approximation they'll work. Crystals do have spurious responses that can cause mode jumping, and these responses don't necessarily map the same way the overtones do, so using a 20MHz crystal at 100MHz may or may not work, depending on the luck of the draw. Other than that I don't know of any differences.

IIRC Digi-Key has 100MHz crystals, but I may be remembering 100MHz oscillators. YMMV. IDNKWTFIAS. Caviat Emptor (so _that's_ what CE means! Here I thought it was a quality mark). Etc.

Tim, would a 100MHz oscillator module do for you? See DigiKey
CTX318LVCT-ND, for example.

Cheers,
Tom

You can use a fundamental mode crystal as an overtone oscillator, but
even if you can get it to oscillate, it won't be generating an
overtone at 100MHz, since overtone modes of oscillation aren't
harmonically related to the fundamental. It's more like the slab of
crystal is vibrating like the drumhead of a steel drum with small
areas of the slab vibrating at higher frequencies, instead of the
entire slab virbarting at just one frequency.

Check out "Chladni patterns" if you're interested.

Here's some pattrens for violin tops and circular plates:

In an AT cut crystal the overtone modes are close, but not exactly on,
the odd harmonics of the fundamental. Furthermore, all of the
literature that I've read on AT cut crystals reports that they vibrate
in the bulk of the crystal, in shear mode -- see figure 7 here:
http://literature.agilent.com/litweb/pdf/5965-7662E.pdf.

Perhaps you're thinking of SAW devices?

I don't know why off-the-shelf crystals are needed when Jan Crystal (Ft. Myers FL) will make the crystal to your specifications in a few days for the same amount of money. They can do fifth ot at 100 MHz. quite easily.

No, I was thinking they vibrated in thickness compression. Thanks for
the correction.

One effect to watch out for with use of unspecified
overtone modes is that the behavior of the resonator
is not ideal; the presence or size of nearby spurs and
the Q depend on how uniform the thickness is that
determines frequency and the placement and size of
contact metal. The wavelength is typically much less
than the dimension along the non-shearing axis, so
having a single mode of resonance near the nominal
frequency or its overtones is not guaranteed, except
by careful construction and verification. So, clearly,
a guarantee about the behavior near the fundamental
resonance cannot be extended to the overtone modes.

If I was trying to build a stable and pure oscillator
operating at a crystal overtone, I would buy the
crystal specified for the overtone I would be using.

Overtone crystals are mechanical resonators and the overtone shear mode which has additional shear planes within the volume wont occupy exactly the same volume as the fundamental so the frequency will not be exactly 3X or 5X the fundamental but approx 2000ppm high or low?
The fundamental crystal will not be so accurately polished or dimensioned as the overtone so it will not go well if at all also it may have higher levels of spurious.

Tim,

to get optimum performance one would grind the 100MHz 5.OT finer or
even polish it, and the thickness of the electrodes might be different
to get optimum Q.
But you should be ok by using a 20MHz fundamental in its 5th.

There are also manufacturers that make 100 in fundamental (up to about
200MHz), and many should have 100 in 5th as standard part...

God says all your good deeds are as filthy rags. Being benevolent is only half the commandment that Jesus gave to us. Ill let you find the other half. But benevolence without God is only motions. God says all have sinned. ALL. You, me, others that will read this. If we sin once and only once in our life, we need a Savior, because we cannot enter into the presence of God with sin on us. So GOD sent Jesus to take our sin upon Him. Jesus went willingly. He could have just said no. You talk about risking your life to save others. How about Jesus GIVING His life to save you from eternal damnation? If that isn't love, then I don't understand love. Yeah, Ill follow that God. Will you? Your choice, but be careful. Just because you don't believe doesn't make God untrue.
Brian Oakley

Jan's what I was about to suggest. I thought the rock I needed would
have been off the shelf, but they made it and sent the test results.

Hello Tim,

As Douglas said the frequency may be a bit off unless you get a crystal made for 5th. An alternative for the 20MHz garden variety would be to make a 20MHz oscillator, run it into a fast gate and fish out the 5th the old fashioned way, with an LC circuit. Then run that through a gate again if needed.

Regards, Joerg

Along the same thought train - I built the t-tec transverter last year. I did fine with it using my scout. This winter my project is to build the the t-tec qrp kit 1320 to drive the xvtr - Im about half way thru with it. when I done I will use it for both monitoring the fifty meter band and qso ing in cw on 50.095 kcs but the down size is that I will only be able to use cw. So you might try a ramsey kit i cant remember if thier kit for 20 meters has ssb or not. For an experimantal antenna I just split some stereo wire 56 inches on each side and took a few laps around a medacine bottle. MFJ has an inexpensive two meter 5/8th verticle that is a quarter wave for 6 meters. These are just temp.ants for testing your kit. I realy think that when the band is open you could just throw out a couple feet of wire (for listening only) and do well.

good luck

Depending on whether the circuit is designed for overtone oscillation or harmonic generation, how perfect the overtone crystals are, and how the circuit is tuned, I'd expect either:
1) No oscillation
2) Very close to 100.1 MHz
3) Very close to 100.3 MHz

What did you experience?

>There are also manufacturers that make 100 in fundamental (up to about >200MHz), and many should have 100 in 5th as standard part...
High frequency fundamentals are real and can be purchased to at least 250MHz note they are expensive, their Q which is ultimately material related reduces with increased frequency (loss is per cycle) such that it may be no higher than a SAW resonator . Still better than a SAW as the temperature coefficient for the SAW only has the linear cancelled whereas the AT cut has the parabolic term cancelled.
Finally the 5th overtone will only pull 1/25 times the fundamental.
Finally finally the SAW can be run at much higher power levels so noise floor is much better.
Finally finally finally a SAW needs a mask which gives a high up front cost and lead time.
The difference in frequency for overtone /X fund may be much more than 2000ppm where the plate is not very parallel and the plate back and electrode diameter non optimum. Beware AT cut strip crystals ie a long section of a circular diameter these may not like overtone operation.

not pull with external reactance change perhaps a byt

Yes depends on electrode diameter plate diameter plate back (electrode
thickness) and parallelism. ie I would not be surprised at 10000ppm.

Hi Doug, great to hear from you and the info in your posts. I'm currently using a SAW at 660 MHz for the clock in a 9951 DDS. Actually, it's better than my 200 MHz 7th overtone tripled to 660 with an MMIC although I do think my MMIC tripler is most of the culprit.

Reason for the post, I think you've changed ISP's on me again, my mail to you gets bounced. Would you pse address me a short note to the e-mail address and give me the current one? That is, if it's not me you're trying to get rid of!

Regards

>>> You can use a fundamental mode crystal as an overtone oscillator, but
>>> even if you can get it to oscillate, it won't be generating an
>>> overtone at 100MHz, since overtone modes of oscillation aren't
>>> harmonically related to the fundamental.

There is a related phenomenon in the field of piano tuning. It has long been known that overtones (called "partials" by piano people) of piano notes are not exactly related to pitch of the fundamental frequency by whole numbered ratios. Instead they are related by factors like

1.000
2.003
3.007
4.018
5.039
6.092
7.211
etc.

The amount by which this series deviates from the ideal whole-numbered ratios is called "inharmonicity" and it differs from one string to another. The stiffer the string, the more inharmonicity. Long thin strings, as are found on harpsichords, have almost no inharmonicity. Short strings in the highest section of the piano have the most inharmonicity. Since one of the goals of piano tuning is to make partials of different notes come out the same, this phenomenon of inharmonicity makes piano tuning inherently more difficult than instruments that have no inharmonicity, like pipe organs.

What is perhaps more like quartz crystals is carillon bells. They are tuned at the factory, and each partial is tuned independently and separately by grinding away metal from different levels on the bell. In view of these related phenomena, it is no wonder that overtones of quartz crystals are independent of each other and from the fundamental.

There is a whole science of crystals all on its own. When they make a
crystal they make a thin disk of material. You would normally expect the
edge of the disk to simply be at right angles. Instead it looks like
this:

****
*
*
*
*
****

The exact angle and depth of that chamfer is how they control which
overtones are selected for and which are supressed. In fundamental
crystals, the maker usually grinds the chamfer so as to reduce the 3rd
harmonic responce.

No, its more like a jello when you jiggle the dish side to side. The main
action of an AT cut is shear mode. In the harmonics, the motion looks
kind of like this:

>>>>>>>>>>>>>>
<<<<<<<<<<<<<<
>>>>>>>>>>>>>>
<<<<<<<<<<<<<<
>>>>>>>>>>>>>>
<<<<<<<<<<<<<<

If you think about the top two lines of text in my little drawing. I
think it is obvious that if the maker thinned it down by one line of text
just as you come to the edge, that portion of the crystal would not work
well at this harmonic. This is what they do in crystals intended for
fundamental operation. It knocks that activity down by several dB at the
overtone. This makes it very unlikely that a simple oscillator will take
off at an overtone.

Yes

In the ideal AT cut crystal "c mode" shear is the only activity. In the SC
cut, the "b" and "a" modes appear. The extra complexity of the mode
selection circuit is part of the reason that SC based OCXOs cost so much.

Sorry, dude, 50 years of designing with crystals, right from when I ground my first surplus WWII rock on a piece of glass with toothpaste as the abrasive says that what the original poster asked is correct.

Will the harmonic be precise? No. Will it be "close", which is what the original poster asked? You bet. Depending on the oscillator circuit, can it be "pulled" on frequency? Perhaps.

But to say that the crystal doesn't resonate anywhere near the harmonic is, as I said, bullpuckey.

When you look at older (pre-PLL) VHF communication gear of the more professional kind they didn't use 5th or higher overtones but employed frequency multiplier stages. For good reason, one being the offset you had mentioned. I'd never run a crystal on its umpteenth harmonic and always designed in multiplier stages like the radio folks did. With today's cheap logic chips that doesn't even cost much in extra parts.

>and that you replied with:

Interesting factoid: I was looking to experiment with 100MHz oscillators largely as a clock source for my own AD9951 experimentation (using the AD9951's built-in PLL multiplier at 4x). I was hoping to experiment a bit with 20 MHz crystals I already had in hand before ordering some "real overtone" crystals cut just for me. I've been looking at AD app note AN-419 and it's Butler oscillator, in particular, although the clock input of the AD9951 probably has different requirements than the AD9850 targetted in AN-419.

Does the AD9951 really work at 660MHz? I thought it was only good to 400MHz...

So far my experimenting has used the on-chip oscillator at 25MHz and the PLL at 16x to get to 400MHz.

> Actually, it's better
> than my 200 MHz 7th overtone tripled to 660

We bandied about "non-harmonic" relations here but how you get from 200 to 660, I don't know.

Tim.

It did oscillate. I was some really oddball frequency inbetween but as
I recall it was neither the mean nor any other obvious relation. I
suppose it was where their response curves complimented but I'm not
sure. Did it only for curiosity's sake to see if it they could be used
for filtering but tried making them oscillate for fun. I know, simple
pleasures... ;-)

The built-in multiplier is quite noisy and makes the 9951 run terribly hot.
>
> Does the AD9951 really work at 660MHz? I thought it was only good to

Yes, if you DON'T use the on board multiplier. I've had it to 750 MHz just to check it since I had heard of some DL's overclocking it to that frequency. Properly heat sunk to the eval board, and without the multiplier, it's cool as a cucumber. AD rates it only to 400 MHz but a sample of 6 units all operate well at 660 MHz.

Well, this one is a 220 MHz 7th overtone from ICL specially surface treated for low noise and operating in a Stephensen bipolar/FET Butler. But as I mentioned to Doug, afraid my MMIC tripler makes a bad job of the 660 output despite a 3 pole final filter. The SAW is not near the Q of the crystal, but the SNR is much better.

Regards

Often cheaper to multiply up than buy an expensive 5th overtone that was
difficult to pull onto frequency and fussy to set up.
The exception would be current and size saving for some portables.

Hi,

As I would like to take advantage of the recent increase in
the 40m allocation here in the UK, I wonder if anyone has made
any sense of the diode table (D8 - D12) on the TS-850S digital
board schematic. This as far as I can see determines the
destination region and thus the rig's operating band limits.

I know that it is possible to change the existing arrangement
to give general coverage to the transmitter but would rather not
do that. Initially I did a hex dump of the ROM but found it too
big a task to decode without experience with the particular
processor code - a uPD78C10.

> was difficult to pull onto frequency and fussy to set up.

And these special cuts can indeed be fussy. They can also be a procurement nightmare.

> The exception would be current and size saving for some portables.

Even then it could be done. Besides the discrete solution there are blazingly fast logic inverters such as the ALVC series. These are usually under 20 cents and come in the super tiny TSSOP format. Now I just wish they had unbuffered versions to do the oscillator part with. If a 74HCU04 is needed for other jobs on the board it could run the oscillator but for any reasonable speed these require more than 4V.

>as I said, bullpuckey.

This reminds me of a colleague who can easily tell everyone
qualitatively that a situation deviates from theoretical ideals and as a
result (using my words and not his) "$#!+ (poop) will splatter!" But he
at least often in my experience have trouble saying this quantatively!

For one project, I decide to try something, and tell my boss what I am
trying. This colleague of mine says (using words of mine and not his),
"slop will spatter"! (As in light for adding optics to a light source for
a specific application. This application has multiple LEDs shining onto
an optical device with multiple elements.)
Boss tells me that what I delivered to him and he found working should
not have worked according to this colleague of mine, due to stray beams
forming. So what do I do - I send photos to the boss of the beam pattern
including the stray beams predicted by my colleague. I even named these
stray beams after my colleague. But they were minor due to most light
produced by the light source being on paths that resulted in adding to the
desired beam combination as opposed to the undesired stray beams.
Furthermore, my boss's industrial designer designed a baffling system
that blocked the small amount of light from the multi-element light source
that was on paths towards the stray beams as opposed to the desired rays
that were "on course" to be utilized by the multi-elemt optical assembly
as planned.

So beware that the situation may not be much worse than ideal when
someone can tell you how you are deviating from ideal!

Now suppose someone makes a crystal oscillate in some overtone mode that
the crystal manufacturer recommends against and is predicted to be
"inharmonic" but turns out to be only a few hundred or even sometimes a
few 10's of KHz from a multiple of a frequency that results from being
used as directed?

As I said in different words in a different post - correctly predicting
that $#!+ (AKA "slop") will spatter does not necessarily that much will
spatter nor that any will spatter far, and maybe in many cases it is

doubtful that both much will spatter and that much will spatter far.

I did my volunteering back in the mid- to late-'90s. I'm long past the
point of being burned out. I used to keep a blacklist of recipes for
the procmail filter that I ran on my unix shell acct. I used to get the
original King of Spam, Spamford Wallace's Cyberpromo spams. He's
recently been in the news for infecting PCs with a spyware in order to
sell them a spyware removal program. Dirty, stinking, filthy,
ex-spammer rat!

BTW, there are spam filters that will run under Procmail or Perl
scripts. Check them out, especially if they're Bayesian filters.

All, at some level, accountable and trustworthy? Not really. The first
spam was in 1978, so there were problems from the beginning.

Basically what you have is the virtual world has become a microcosm of
the real world. Nothing more, nothing less.

In order to be constitutional the law has to meet certain criteria. One
is that it has to put limits on commercial speech without being
burdensome. The law has to be explicit enough to keep itr from being
defeated on appeal.

> - It preempts most State laws which had stronger restrictions on
> spamming, and therefore makes legal certain spams which were
> previously forbidden by State law.

For five years, Calif had laws that were on the books but were
unenforced. They were challengd as unconstitutional. They and 35 other
state laws weren't consistent, making it a mess for the courts and
lawyers in every state. We had 36 different tools but they were largely
unused. Now there is a consistent set of national laws with much better
chance of being enforced. Someone has to light a fire under the feds to
get them to step up the enforcement. All this bitching, whining and
nmoaning about what used to be and how bad it is now is a huge waste of
time. Get over it and proceed on with the tools given to us, and hammer
the spammers.

GB,

Thanks for that address and the 78C10 info. Have emailed them over the modification and await results. If I don't get anywhere, I'll extend the diode array out to a proto-board and play around until the sweet-spot shows itself. What I'm looking for really is the North American setting as they have had the extended 40M allocation from the start.

Cheers - Joe, G3LLV

There was very little until the 1990s, and if the first spam was in 1978,
then we had about 7 years of good networking before there was any.

Horse exhaust.

You-Can-Spam, under the guise of improving the situation by applying one uniform law everywhere, forced everything into one badly-fitting, Procrustean bed, overriding and effectively nullifying existing state laws, some of which (Washington, California) were *very* much better written and more effective.

Yes, those laws got challenged as unconstitutional. A challenge by itself means nothing; it's the *OUTCOME* of the challenge that means something, and the Washington and California laws survived all the challenges against them. It's because they survived those challenges, thereby putting fear into the cryostats[1] of the folks who run the advertising industry and of the Senators from Coca-Cola, Time-Warner, and the other big owners of federal legislators, that You-Can-Spam came to be.

Private right of action used to exist because of state laws, but that right now has been removed by You-Can-Spam, and only providers and Attorneys General have standing to sue.

You-Can-Spam is tailor-made for the advertising industry, which comes as no surprise to me, because the folks who really wrote it certainly appear to have been advertising industry lobbyists.

If you don't like all the bitching, whining, and moaning about what used to be, then you have the right to move somewhere that prohibits it. Choose carefully: places that prohibit it may not let you move out again. Me, I'll stay here and bitch, whine, moan, and lean hard on my congresscritters.

[1] We can be quite certain that they don't have hearts. A heart is
not capable of pumping liquid Helium.

1422. Re: Using non-overtone crystal in overtone mode?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-02 16:08:18 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <d04odi$2vc$1@titan.btinternet.com>
Source record: 19954
Cross-posted to: sci.electronics.design,sci.electronics.components,rec.radio.amateur.homebrew

A solid slab of crystal naturally oscillates at frequencies at which one of its three dimensions, length, breadth and thickness, is a mechanical 1/2-wavelength. It can easily be induced to oscillate at harmonics of the fundamental.

It can also oscillate in one of several mechanical modes, eg., longitudinal, breadth-wise or in torsion. And in shunt or series-resonant electrical modes.

The circuit it is embedded in can encourage a preferred frequency. It is easy to select harmonics. Self-preference is also given to the frequency which has the highest Q, ie., the least mechanical loss. This is usually the fundamental.

It does not oscillate EXACTLY at multiples simply because it has three dimensions and Length, Breadth and Thickness slightly 'interfere' with each other.

A poorly cut crystal, eg., lack of parallelism, at which there may be no strong preference may jump erratically between two non-harmonically related frequencies.

Frequency versus temperature curves depend on oscillation mode and on the angle at which the slab is cut relative to the direction of the individual crystals in the bulk material lattice as found by optical means. Cubic curves are best because they contain a flat horizontal portion.

One of those nice ceramic or equivalent coil formers with moulded-in
cut-outs for each turn of wire.

This is for a HF PA coil.

Ideally larger OD than 70mm and longer than13cm.

I'm unable to wind a large enough inductor on the one I have here
(65mm x 13cm).

It can only hold 26 turns with roughly 1-turn spacing.

Dig through your junk boxes please.

Did the audio go through a LPF for the phasing unit?
Remember that a square wave is made up of the sum of many harmonics -
most of these will have been removed and the amplituyde of the
fundamental may not be that large.

Hi,

This Bill Orr article may be what you are looking for -

http://www.thecompendium.net/radio/SW-3/SW3maginfo.pdf

Incidently, the large choke in the audio coupling circuit is
there to obtain as high an AC gain as possible at the expense of
a relatively low DC voltage drop. The fact that the grid leak and
coupling capacitor are all part of the same assembly suggests
that National used the same arrangement is several designs.

Cheers - Joe

From: "G. Doughty" <ki4bbl@cox.net>
Message-ID: <E4LVd.34556$7z6.2389@lakeread04>
Source record: 19961

I have an issue on 40 meters from my tentec scout 555. After the rig is tuned (mfj 901b) and I tx cw, I get an AC hum in my headphones on every key down. This doesn't happen when my audio comes from the rig. I am using an alpha delta loaded antenna in the attic and it is almost certainly putting the tuner to a test. Is there something I can do to alleviate this problem?

Thanks
greg

So where are your headphones plugged when you hear the hum?

When I'm sending CW on my Icom 751 at full power with the tuner loaded for very low SWR, I hear a pretty good AC ripple over the sidetone. I think it's because I'm dragging a lot of power out of the supply, and it doesn't regulate as well at those power levels as it does at lower levels.

It's not a high enough level to make me think it's a problem; I don't know about your hum, but wonder what a scope would show.

Since you are using an attic antenna, I guess that you must have quite
a large RF field strength inside the house. When there is a headphone
cable connected to the transceiver, quite large RF voltages can be
induced into the wire, feeding it into the headphone jack and possibly
causing some havoc inside the rig.

During a QSO, did you ask about any hum in your transmission when the
headphone was used or when the speaker was used respectively ?

What exactly happens is hard to predict on this description, but here
are some possibilities.

If your rig and antenna are badly grounded, the RF current induced to
the headphone wire will flow through the rig signal ground to the
power supply rectifiers and through the mains transformer stray
capacitances to the mains neutral and then to the ground. Since the
rectifiers are not conducting constantly, but will cut off 100 or 120
times each second, causing some hum. This has been a problem with some
mains operated receivers, requiring some capacitors across the
rectifier diodes or a proper grounding. However, I have never heard
about this with transmitters.

Depending on the wiring code used in your area and if separate
grounding electrodes are used for your antenna and electric system,
some neutral current may flow through your rig to the antenna ground
electrode and from there to the mains ground electrode. This might
cause some strange effects in some special situations especially with
resonant wire sections in the house wiring.

The first thing to try is to wind the headphone cable around a ferrite
rod very close to the headphone plug and check if this helped. Also
putting some ferrites on the power supply mains and/or DC may help,
since apparently there is a quite high RF field strength around, due
to the attic antenna, which can cause all sorts of problems that might
be hard to diagnose.

Ferrite isolator clipped around your headphone lead at input to rig should
do the job.

I've been searching for some hints as to what may be in the resin-encased amplifier used on the Wellbrook loops without much luck. Their power demand of 130 mA at 12 volts is kind of high for any FET diff-amp, PNP level shift, into a balanced to unbalance output transformer arrangement. I'm using that configuration right now on a tuned loop that only requires 17 mA at 9 volts. Any ideas or links to useful information?

Thanks,

Chuck, w6pkp

Hi Chuck,

The hi Ic is usually indicative of a CATV device being run in a hi IP3 mode.
The preamp I am using on my 7' shielded loop was originally published by
Burhans and described in the 1985 June Lowdown- using a J310 followed by a
2N3904 and a pair of Mouser audio tranformers both IN and OUT. The URL
appears to have gone away- I can send the schematic if you are interested.

1443. Plan 9 from EMI space?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-05 06:18:57 UTC
From: eternalsquire@comcast.net
Message-ID: <1110003537.443544.115380@f14g2000cwb.googlegroups.com>
Source record: 19975

Hi all,

I've done the google search already, so I hope maybe one of you has an answer.

I am in the beginning stages of setting up my station, and I am getting lots of EMI from various applicances in the apartment. I used an SW pocket radio as a sniffer.

It turns out that most of these are throwing out hash back into the AC line,
and that the AC wall conduits are conducting EMI into the room my wife allows me to use for my station. My station is on the other side of the apartment, but it doesn't matter about the physical distance because the
AC lines are throwing off the worst of the noise. I turned off EVERYTHING
and was able to reduce the problem enough to hear CW on the 7.050 on my

pocket radio without an external antenna.

Throw everything on, and I could barely hear the signal with antenna, because
EVERYTHING is going back into the house wiring!!!

>From worst offenders to least worst, they are:

1) GE Hotpoint refrigerator/freezer.
2) Air conditioning system.
3) Aquarium pump.
4) Overhead florescent lights.
5) Microwave oven (even in in standby mode!).
6) LED alarm clocks (3)
7) Telephone answering machine
8) Cordless telephone base station (900 Mhz)
9) Cable Modem
10) Wireless Router
11) Late model Computer and CRT Monitor.

I have the following assets:

1) I live on the lower floor and have a water pipe just outside the window
of my station room.

2) I just bought 4 each of 3 amp and 30 amp CORCOM line filters on Ebay.

3) A bunch of FT-50-43 cores.

4) My wife's loving patience.

Questions:

1) Ferrite 43 material is supposed to attentuate for 20 Mhz and up, and the
frequencies I want to hear are at 80 thru 20 meters. Should I use the 73
material instead for wrapping AC cords around toroids for common-mode
chokes?

2) Do modern refrigerators in apartments use ordinary AC sockets or
3-phase?

3) I have a 1500 watt microwave oven, can I have it also run off a CORCOM
filter?

3) Can I use a CORCOM filter to isolate EMI from each appliance (30 AMP)
and from the aquarium pump (3 AMP) from the AC lines? Or, do I also
need common-mode chokes?

4) I split the wall wires of the wall wart and would each polarity around
its own FT-50-54 about 4 times. Will this be remotely as effective as
winding the wall-wart cord around a larger toroid?

Suggestions, anyone?

Thanks,

The Eternal Squire

It would be an unusual residential apartment which has 3-phase AC service of any kind directly incoming to the individual apartment. Large apartment buildings and complexes may indeed have 3-phase service from the power company, but the electricity would go through distribution transformers in the building before it ever gets to your apartment. 3-phase AC from the enduser point-of-view is used primarily in large commercial and industrial applications for things such as machinery, elevators, high-power transmitters, HVAC, etc.

Your apartment itself is almost certainly fed some sort of 208 VAC (or thereabouts) single-phase 3-wire service where there are 2 "hot" wires and a neutral. The higher voltage for electric ranges, etc. is taken between the two hot conductors while 110 VAC for everything else (such as the refrigerator) is 'derived' off of either one of the hots against the neutral and would be wired to appear on the 2 parallel prongs of an "ordinary" AC wall socket. [I'm presuming you live in North America where we have 110 VAC devices, as opposed to Europe or other overseas locations]

Not just apartments, but few residences of any type get three phase
power.

In fact, people who want to have a shop with three phase power usually
need to have it added. The usual power setup for residences is what
you have described. 70-200 amp, 110VAC single phase is typical supply
for a home or apartment. The newer the contruction, the more amps in
the supply.

Happy trails,

hi!
i've always wondered what phase-shift there is between those two 110V lines
in an USA 220V AC net system.

here we have either one phase of 230V or then 3 phase
with 120 degrees between the phases.
230V between phase to ground or 400V (third root of 3 times 230V of course)
between phases

everyone has direct 3-phase system with 230V to ground in every apartment or
house splitted up to equal load on the phases.

cheers
as

There cannot be any, as they come off the same transformer.

A few appliances in most houses use the full 220 VAC, such as electric
heat, clothes dryer, electric range or oven, so there cannot be a
phase differential.

Industrial electrical installations are a different thing entirely,
even if they come off the same grid and substations as nearby
residential areas. IIRC, power comes to the substation as 480 3 phase,
and it is what happens after that varies between residential and
serious industrial.

Many electricians here do little industrial electrical work after
their testing and concntrae on homes, and there are a few who
specialize in industrial work.

Happy trails,
Gary (net.yogi.bear)

Actually, the lines are opposite phase (180 degrees), 110 VAC RMS relative
to neutral/ground. If they were the same phase, then your 220V appliances
would see 0V.

The phase shift in the Western hemisphere residential power
distribution system is 180 degrees, since the system is basically a
single phase system, with a 2x110 V secondary, with the centre tap
grounded.

The rest of the world is using some three phase systems for
residential distribution, either 127/220 or 230/400 V.

My bad.

I don't really think of 180 as a phase shift, as much as a reverse
polarity.

Of course, both are true.

The three wire supply coming into the house is pretty standard in the
US residential electrical service, with +120/neutral/-120.

Chances are that your apartment structure is not using metal
conduit for the AC lines. That helps quite a bit but is NOT an
option for a renter. :-(

>From worst offenders to least worst, they are:
>
>1) GE Hotpoint refrigerator/freezer.

>7) Telephone answering machine
>8) Cordless telephone base station (900 Mhz)
>9) Cable Modem
>10) Wireless Router
>11) Late model Computer and CRT Monitor.

Typical household using modern appliances...all with little
electronic
circuits in them generating wideband RF hash. Very good for
reducing the "standby" load to the power company (energy
efficient if they have "power factor correction" circuits) but a
total
#$%!!! for anyone wanting to receive MF to HF signals near them.

>I have the following assets:
>
>1) I live on the lower floor and have a water pipe just outside the
window
> of my station room.

I doubt whether that will help in any real way, except for possible
lightning strike re-direction. Leads to the (grounded, supposedly)
water pipe are inductive and little antennas by themselves.

>2) I just bought 4 each of 3 amp and 30 amp CORCOM line filters on
Ebay.

Seriously, anyone saying "those always work" are probably selling
line
filters. It's a case of trying them out to find out if they do in
that case.

>3) A bunch of FT-50-43 cores.

Better than nothing.

>4) My wife's loving patience.

PRICELESS! Keep that at the expense of everything else!

>Questions:
>
>1) Ferrite 43 material is supposed to attentuate for 20 Mhz and up,
and the
> frequencies I want to hear are at 80 thru 20 meters. Should I
use the 73
> material instead for wrapping AC cords around toroids for
common-mode
> chokes?

Probably, but I suggest trying the 43 first. ANY attenuation at the
offending appliance is better than none. Do it as close to the
appliance as possible, lessen the RF hash dribbling out the lines.

>2) Do modern refrigerators in apartments use ordinary AC sockets or
3-phase?

Both. Depends on model and size. Wife and I had a TOTAL makeover
of our kitchen and laundry alcove in 1999, outlets were on the list
to
check for all new appliances in case of rework of residence wiring

was
needed. We now have an un-fancy fridge/freezer with "old" control system, minimum of EMI-generating circuitry within, no bells or whistles. Most residential refrigerators seem to use 115 VAC single phase with conventional 3-prong connectors. I say "seem to" based on
a three-inch thick notebook of kitchen appliance data researched 5 1/2 years ago.

The front-loading washer and dryer in the laundry alcove had the ordinary synchronous motor driven timers/cyclers, no bells and whistles with little electronic clocks or other dinguses added on (big sales feature in the stores, like seeing digital time is a big plus).

>3) I have a 1500 watt microwave oven, can I have it also run off a CORCOM
> filter?

The 30 A version; 1.5 KW will draw about 14 A through the line. A problem there is that the line filter should be grounded to something close to ground (like the old Los Angeles electrical code which mandated metal conduit everywhere). The case of the microwave is metal and it has lots of shielding for 2 GHz RF.

On the other hand, it may be just the clock/timer/controller that is generating EMI and that is rather low power. All of those use a microcontoller for all those selectable settings and probably have their own internal DC supply in parallel with the heavy-duty magnetron supply. All bets are off if there's a "power factor corrector" circuit in that supply for the maggie...those are modified switchers and may or may not be EMI generators.

>3) Can I use a CORCOM filter to isolate EMI from each appliance (30 AMP)
> and from the aquarium pump (3 AMP) from the AC lines? Or, do I also
> need common-mode chokes?

Again, it's a matter of where to connect the ground/common of the line filter. Filter ground to metal conduit ground works fairly well but
unknown on Romex wiring or PVC conduit electrical line routing. One has to experiment there.

>4) I split the wall wires of the wall wart and would each polarity around
> its own FT-50-54 about 4 times. Will this be remotely as effective as
> winding the wall-wart cord around a larger toroid?

Probably, but that's again a matter of experiment. Ain't NO absolutes

when there's all those other environment unknowns.

Ferrite or iron powder material, any kind, will REDUCE the EMI but none of them can eliminate it completely. Commercial equipment that must meet government radiation specs will use the least amount necessary to save costs and they rarely publish data on the amount of
reduction. All have to experiment with it. For what it's worth, a large toroid can be an advantage in stringing the wall-wart lead-out through it, forming a large common-mode choke. It also costs more. <shrug>

=======

From my own experience in a metal-conduit-AC-line house built in 1962, the worst EMI offenders are the "efficiency" light bulbs which

have switchers of some sort inside their bases. Some brands are low EMI (sold under the GE label), others are high EMI (sold under Philips label). It's a "caveat emptor" thing. :-(

I've done the portable all-band receiver sniffing here (borrowed wide-
band scanner type) and found few real offenders at several feet from their locations. Offhand, I'd say that metal conduit AC distribution
is a real help in reducing EMI. Appliances that include microcontroller devices in all the clocks but one, a bells-and -whistles Amana microwave, a Braun coffee maker (replacing a venerable Mr. Coffee), digital light timers, TV cable set-top box, VCR, cordless phone, combo FAX and phone recorder, electronic thermostat for furnace/air system, radio-alarm in bedroom. All of those do produce some EMI but the sniffer has to be right on top of it for detection. The gas furnace has an electronic ignition which makes an obvious spark, as do the range-top burners in the kitchen; never thought to sniff for those but I've not heard any obvious EMI from those.

An ancient-but-still-in-spec Icom R-70 sits on the arm of a desk in the office room with a fluorescent light bar (two 40 W tubes in an L, home-built) right above it. When the outside long-wire blew down I tried the 8-foot aluminum window frame above it as an indoor antenna and got incredible EMI hash. Fluorescent lights in the kitchen (two) and in the attached garage (also two) are very minor sources of EMI here. When connected to the outside long wire there was no problem light on or off. That includes the kitchen fluorescents, close to the outside coax connection to the long-wire.

Replacing my computer's CRT monitor with an LCD flat monitor helped reduce EMI spritz from my computer. My wife saw the nice thing I got (special sale at Fry's), she wanted one for her computer too! :-) That dropped the internal EMI level (R-70 hasn't been

connected to an outside antenna yet) some more. Both computer boxes are nicely-shielded-case HP Pavilions with internal modems and such...not like the el cheapo PC box obtained in 1998. There are some EMI bursts from the external flat-bed scanner and the inkjet printers but neither scanning nor printing is done at the same
time as receiving HF RF (scanner has its own outside antenna). Battery-powered radio clocks don't seem to radiate much of anything except the correct time. :-)

Using a conductive chassis/enclosure and incorporating any kind of line filter in a piece of equipment will help reduce EMI both coming and going. The line filter common is made right to the chassis/ enclosure and that is the best connection. If the residence has Romex or equivalent wiring, chances are that an HF transmitter will be the major EMI cause for OTHERS, especially in an apartment building. That's worse if the Rx/Tx antenna is IN the apartment.

An outside antenna (if possible) will reduce EMI garbage input to any receiver, any user's environment.

==========

"Outer space" is only a half-hour's drive away...if your car can go straight up... :-)

Source record: 19985

Does anybody have alignment notes on this receiver. Another eBay special that was "working perfectly, but as is". I need to know how to set the carrier injection frequency of the BFO. LSB injection is at the edge of the I.F. passband, resulting in not being able to demodulate these signals. I did adjust the reference oscillator while in the test mode, so that part is ok.
According to the schematic, it appears that the reference oscillator is divided by N so arrive at the carrier injection frequencies but I am not sure. It could also be an I.F. filter that has developed an assymmetrical response. Another thing could be that the 2nd LO is off frequency, but since the BFO is injected at the 455kHz I.F. this is highly unlikely.
Anybody have any experience with this type of situation?

Pete

1457. (BPL) Virtual Spectrum- Global Test

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-06 16:34:19 UTC
From: David Stinson <arc5@ix.netcom.com>
Message-ID: <fiGWd.56697$uc.29149@trnddc03>
Source record: 19989

I finally got the Provisional Patent filed for
my BPL work-around, Virtual Spectrum (tm).
Server is up and running and everything is ready.
Next step- some friends will
help with tests- one in Europe, one in
Australia and two in the U.S.
There will be a low bandwidth and
a high-bandwidth trail. First will
stream a few KCs of 40 meters and include
several CW messages at various frequencies,
including a couple close together so we
can figure the best levels without cross-talk.
Next will be a high-bandwidth trial with
CW, SSB, FM and some other mode yet
to be decided, streaming about 40 KC of
the band. Then, a live, continuous
stream of the bottom 40 KC of 20 meters
from my location, which will run for a few days.
I hope they don't put BPL here in the mean time.

After these tests are concluded,
the next step will be configuring for
2-way QSOs, which is just a matter of
setting up the software and T/R switching.
I ain't had this much fun with a radio project
since I was a novice. :-).

1458. 1N23E vs. Schottkey?? Question

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-06 18:04:18 UTC
From: hexter@blazenet.net
Message-ID: <112mhh2cegm2nb6@corp.supernews.com>
Source record: 19990

This is on a 10 gig receive setup. There is no LNFE, just antenna to mixer direct couple in a balanced waveguide mixer assembly. The question is, if I remove the 1N23E/1N23ER pair, and go with a balanced set of schottkey microwave diodes, this would allow me to drop my local oscillator injection perhaps 6db. Will I see any increased sensativity, or should I just keep the 1N23 setup?

New XP2500A
The World's #1 Digital Satellite Television
Receiver Descrambler is Now Available to you!!!!!

Order Yours at: http://www.fta9000.3322.org

No Monthly Subscription Charges of ANY Sort!
No Service Contracts of ANY Sort!
No Telephone Connections of ANY Sort!!!!
Does NOT use ANY Sort of Satellite Access Card
The World's Number One "Cardless" Satellite Receiver!!!!

A NEW Product for the NEW Year of 2005
Our New XP2500A Digital Satellite Television Receiver Descrambler allows you to view at your convenience the following with the USA, Canada, Cuba, Bahamas, Jamaica, Virgin Islands and Mexico:

View Over 600+ Digital Television Stations FREE! (Everything!)
View Over 200+ Digital Commercial Free Music Stations FREE !(all categories)
View Over 40 Pay-Per-View Movies Channels FREE!
View 8 HBO's/5 Cinemax's/10 Showtime's/8 Starz, etc. FREE!
View Seven Adult Channels FREE FREE FREE • 24 Hours A Day (Non-Stop Action)!
Boxing/Football/Soccer/Baseball/Basketball • ALL Sports Packages FREE (With No Black Outs)!
Receive Home-Town Local Broadcast Television Stations from 4 Time Zones
Use this New Television Descrambler at Home/Office/Truck/RV etc.
Works In the USA and Canada • plus ALL of North and South America and Territories!
Works on: Nagravision, Seca, Viaccess #1 and #2, Irdeto One and Betacrypt Digital Satellite Signals!!!!

NOTE TO AUSTRAILIANS: We get many request about the Australia•s "Foxtel Channel". Our New XP2500A Receiver works nearly ANY where in the world - but it will NOT receive "Australia•s FOXTEL Broadcast Channel" as of yet.....they use Irdeto #2 a Decoding System.....so wait patiently - our Descrambling Technicians are working HARD on this one, to brake the code.
International Customers.

Our NEW XP2500A Digital Satellite Television Receiver - NOW UNSCRAMBLES THE FOLLOWING SIGNALS:
ABsat
ABS-CBN
Arabesque (ART)
Astro TV
BBC Prime
C+ NL
Canada's Bell ExpressVU
Canal + France

1463. 70MHz Imagerejection mixer with 2x SA602 (?)

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-07 08:13:49 UTC
From: J M Noeding <la8ak@online.no>
Message-ID: <f23o211molmeqooam13k7o7c1hbvcfvoqk@4ax.com>
Source record: 19995

Hi

have been examining some surplus mobile telephone base station
equipment and discovered that the 70MHz to 455kHz mixers consists of
2x SA602. Since I've never seen an application using two such items,
my guess it for an image rejection type mixer.
Could somebody please guide me into some notes describing such mixer,
possibly using 2x SA602 (and a crystal osc)

Jan-Martin

J. M. Noeding, LA8AK, N-4623 Kristiansand

Jan-Martin , With 2xSA602 ,are you sure there isn't a 10.7 MHz
'intermediate' IF as well ?

An image rejecting mixer requires quadrature inputs (both signal and
LO), two mixers, and summation of the outputs i.e.

sin(A+B) = sin(A)cos(B) + cos(A)sin(B)

Also - you're unlikely to have image problems at the second mixer.

1466. Good fox kit / schematic?

Does anyone have experience with a good (and preferably inexpensive)
fox kit that has a range of atleast 30 miles? I don't have a frequency
range in mind, and am open to suggestions. Any additional suggestions
regarding the best equipment/antenna to track it with is also
appreciated.

Thanks in advance!
Dave

1467. Re: pumping the T2-exciter board with a squarewave signal

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-07 16:47:56 UTC

Source record: 19899

Thanks for replying.

The problem, was that I had not enough LO-power from the 74F74 outputs.
I have buffered them with a 50 Ohm TTL Driver 74AS804 that could deliver
plenty of current into the LO-inputs. I have limited it to approx 10 mA
by a series resistor of 300 Ohm. At a voltage drop of approximately .550
mVpp across the LO-inputs (approx. 5 mW) the exciter works now as expected.

wow, those 1N21/23 diodes are stone age! They are Germanium diodes
and usually have to be biased for lowest noise, best conversion
figure. Also when used in cavities, the diode itself forms part
of the coupling network. The letter in the diode part is a measure
of noise figure, the higher up in the alphabet you go, the lower
the rated noise figure. BTW those diodes a dated from the
1940's!

1470. I Need Instructions to hook up tone encoder

I have a Kenwood TS-711A. I bought the SS-64 tone encoder from
Communications Specialists at http://www.com-spec.com/ss64.htm
They don't have installation instructions for the TS-711A.

I have 3 wires to hookup:

Red: v+
Black: Ground
Yellow: Modulator

The first two I can handle but the yellow I need help with...

I just received the service manual and schematics today but I still can't
find the modulator.
Does anyone know where to solder the yellow wire for tone out?

Thanks,

Doug

You're exactly right: there was very little in the early '90s because
the Net was very little until the '90s. Obviously.

> then we had about 7 years of good networking before there was any.

I'm curious as to what you mean by good networking. And what you mean
by 'there was any'. Like, any _what_? Those two idiots Canter & Siegel
were already spamming Usenet in 1994.

Doug -

You can call ComSpec Tech support.
They have hundreds of Application Notes on file on file.
They are slowly moving these paper documents to the Internet web site.

SS-64 General Product Installation Sheet
http://www.com-spec.com/insheet/ss64inst.pdf

The second page of the SS-64 highlights the CTCSS OUTPUT (YELLOW) (PIN 3)
This output generates the CTCSS encode tone. The most common place to connect this line is just prior to the modulation stage in the transmitter. Typical connections would be to the center of the deviation pot. to the varactor diode in the modulator circuit, or to the manufacturer’s suggested connection point. This connection point can vary from radio to radio. [A schematic of the radio is useful]

Do NOT connect the CTCSS Output to the microphone input as the microphone audio stages will distort and attenuate the CTCSS signal. Since the CTCSS Output on the SS-6.4 is tow impedance, you may have to install a series resistor to reduce the loading effects of the CTCSS Output depending on the interface impedance. This is evident in the case of connecting to the center of a 106K deviation pot. In this case, a 106K series resistor will

compensate for the impedance difference. In addition, a slight adjustment of the voice deviation may be required to compensate for the CTCSS Output circuit loading.

Yes, because in 1993, commercial public access began. There was very, very little spam during the days when the Internet was confined to academia and research labs. Back then, when people talked about "spam" they generally meant announcements that were on-topic but were considered too commercial.

there are 4 receivers, two on each board (with 2x SA604 and 4x SA602),
so I think it is a lot of diversity if it was interesting

What range and what step size? How inexpensive? How accurate? Manual or electrically driven? You can build your own from SMT attenuator chips which are available from EMC Technology, Cherry Hill, NJ, though they aren't particularly cheap (and are good over a much wider freq range than you are looking for, even assuming you mean MHz instead of mHz). You can also build attenuators from SMT resistors: not all the resistors will have to handle 2 watts, and you can series-parallel resistors to get the power dissipation you need. You probably will find that metal-oxide axial lead resistors will work fine for you up to 30MHz too, if you aren't trying to get exceptional return loss.

Cheers,
Tom

Doug,

Of course, NOW somebody comes up with a link for you for a tone board made specifically for your rig. If you don't want to send back the Spec Com board, I think I know an easy way for you to find the modulation point...looking at the board that is a direct replacement for that rig, it appears the tone board plugs onto 7 or 8 pins that must be present in the radio. One of those MUST be the audio input to the modulator. Check the service manual to find the pinout for that connector and you should be home free...

This is probably not that complicated (I hope?!?) but I need a PC program that would just tell a PC soundcard to generate a standard CTCSS tone (example 107.2 Hz) sinewave that could be fed into an older FM amateur transceiver. I don't want to find/buy/build a CTCSS module for it, and will have a PC handy. I imagine a WAV file could be created, but if there is some kind of software (perhaps a "function generator" program) that would be ideal, particularly if you could just give it the frequency in Hz or something like that, and get a steady sine wave out of the sound card.

Very tks,

73 Dave WB0GAZ wb0gaz@hotmail.com

Try http://www.goldwave.com/ for a Windows-based solution
(fully-functional demo version can be downloaded).

For Linux, try http://audacity.sourceforge.net/ (free)

Both of these should be able to generate, and then play, a WAV file
having a sinusoid of almost any desired frequency within the PC's
audio bandwidth. I used Audacity to generate precise sinewaves to be
used when calibrating an FM modulation meter via the Bessel-function
null method.

<snippety>

What you describe is a lot like using a 40mm antiaircraft gun to
shoot down a rubber-band powered model airplane. What happens when you
suddenly need to use your sound card for something other than a PL
encoder?

$28.95 plus a little for shipping will get you a perfectly usable
dedicated CTCSS encoder, as described at this link:

http://www.com-spec.com/ss64.htm

PC's are not, contrary to popular belief, the Answer to All Things
Radio or Technical. This is one area where a dedicated purpose-built
device would be a much better investment of your time and money.

Happy tweaking.

If you are hopeing to get the CTCSS tone through you Microphone,
forget it. The frequency response of the Mic and Modulator will
probably prohibit any success but have a look at this link

http://www.qsl.net/ta2mbd/elektronik/af/ctcss_16c84.htm

It describes a cheap solution to your problem and it does'nt use a
steamhammer to crack a nut.

But, "there was very, very little Internet during the days when the
Internet was confined to academia and research labs." So the effect was
virtually nil.

Or more precisely, if you didn't have any spam because you didn't have
any Internet, then what's the point.

> Back then, when people talked about "spam" they generally
> meant announcements that were on-topic but were considered too
commercial.

But, "back then, when people talked about "spam", there were no people
talking in the general public. In other words, back in "the good ol'
days", there were no good ol' days for the average person.

Dave -

You may be missing the point of CTCSS. It is NOT like "Touch Tone" sounds
that can be insert through the microphone input and pass through the audio
chain.

Never insert the CTCSS Output (from any CTCSS encoder board or source) to
the microphone input of a radio.
The radio's microphone audio stages will distort and attenuate the CTCSS
signal (defeating the whole purpose)

The most common place to connect the CTCSS Output to is just prior to the
modulation stage in the transmitter.
Typical connections would be: to the center of the deviation pot, to the
varactor diode in the modulator circuit, or to the manufacturer's suggested
connection point. This connection point for the CTCSS can vary from radio to
radio. A schematic of the radio is very useful.

Since the CTCSS Output from your sound card may be low impedance, you may
have to install a series resistor to reduce the loading effects from the
sound card (CTCSS) Output --- depending on the interface impedance.
This is evident in the case of connecting to the center of a 10K deviation
pot. In this case, a 10K series resistor will compensate for the impedance
difference.
In addition, a slight adjustment of the voice deviation may be required to
compensate for the CTCSS Output circuit loading.

The CTCSS encoders from ComSpec or PIEXX are easy to install and less than
$50 .

> hi!
> i've always wondered what phase-shift there is between those two 110V
> lines in an USA 220V AC net system.
>
I think the answer to your question is either no phase shift or 180 degrees.
(The two conductors you mention are the two ends of the same phase!)
To explain; coming into the typical North American residence is a three wire
service.
The three wires are the two ends of and the centre tap of a single phase 230
volt secondary winding of the power utility distribution or step down
transformer located nearby. Note 1.
Thus there is 230 volts single phase between the two outer conductors or
legs and 115 volts between each of them and the centre tap. The centre tap
is grounded/earthed at the transformer and again (once only) where the
service enters the house.
It becomes the neutral or zero voltage wire.
Some people, including electricians, incorrectly refer to the two outer
conductors, each at 115v to neutral, as 'Phases'!
They are not and a more understandable designation is 'Legs'.
Typical colour coding is Leg A = Black, Neutral = White, Leg B = Red.
Although this is AC you can, sort of, think of it as Black = Plus 115 volts,
White = 0 volts, Red = Minus 115 volts.
Within the house heavy appliances that require considerable wattage, such as
a water heater or cooking stove are connected to 230 volts through double
pole breakers. (Some also have 115 volt items, e.g. an oven light, so also
use the neutral wire.
Everything in house has a ground/earth (bare or green) wire; which does not
carry any current for safety.
The 115 volt loads comprising lights and outlets are distributed over both
legs in a hopefully balanced manner through single pole breakers. It works
well and the maximum voltage to ground or neutral is 115v AC RMS.
If you want a comparison; think about those single phase safety transformers
they often use now on British construction sites, with 115 volt tools. As I
understand they step down the normal 230v to 115v, that in itself is less
voltage. The centre tap of the 115 volt secondary (again as I understand) is
grounded. Thus the maximum voltage to ground is half the 115 volts. That's
57.5 volts RMS and about 81 volts peak; much safer eh?
So our North American residential service is, sort of, similar.
Any help?
In commercial work you may get into three phase, one voltage used is 347
volts AC RMS e.g. lighting in a say a supermarket.
Note 1. A typical 'primary' distribution voltage from the subsation some 5

kilometres away is around 12.7 kilovolts. The lane behind our house has a single phase 2 wire (live plus neutral) primary; various step down distribution transformers supply groups or individual houses each with a 3 wire 230 volt centre tapped supply. In this area it is all overhead. While o.head distribution can be more easily damaged by weather it is much quicker to repair than underground plant, imagine moving three feet of snow and then digging into frozen ground! And maybe breaking the telephone cable while doing it! The poles are shared with telephone and TV cable systems. Thus in quite small communities we have a choice of internet service from the cable TV provider via their coax, or ADSL from the telco, or dial up over regular telephone etc. In competition with cable TV (analogue and now also digital) we now have two Canadian satellite systems and in many areas of Canada people can subscribe to US satellite services as well.
Long winded answer but hope it helps.
Terry.

Could you use one winding of say an audio output transformer; the primary,
with nothing connected to the secondary?
The primary winding becoming a high inductance choke!
Found that out the hard way one time!
The speaker became disconnected; the primary was in the plate circuit of a
6V6, audio output pentode.
No sound, turned up volume, naturally, like you would!
Result sparks during peaks in the music from the plate pin of the tube
socket to a nearby ground/chassis wire or summat. Ah yes, high inductive
reactance, some audio power and induced voltage.
Lucky didn't burn out the insulated primary of the audio transformer!

>1940's!

Yes, they were used in WWII radars with 2K25 klystron locals,
and we call that generation 1, in the late 70's they quit using
ATR/TR tubes on the lower power stuff, and went with circulators
and diode limiters, but the 1N23E/R remained firmly rooted in these
gen 2 radars until the late eighties. Gen 3 brought about the LNFE/MMIC
front end with a double balanced mixer featuring I/Q phase rejection
in the mixer stage producing I.F. output only when the local osc is
above the incoming signal. These front ends have about 6db gain over
the broadband 1N23 setup, and are much quieter, giving about a 10db
better SNR overall. So now the little Gen3 2.2kw units see targets that
the old 4kw units never could!

Yes this is some older stuff I have, a mid eighties radar front end
with a 10gig hamband gunn local, now back to our regularly scheduled
question, Should I buy $70 worth of matched schottkey, or $40 worth
of 1N23EMR. I have to buy something, my old crystals are way shot!!

hello, i'm relatively new to ham radio and had a few technical
questions i was hoping to throw out...anyone that can answer these
would be very helpful!

1. i've seen transmitter schematics that were simple, and others that
were complex. as a general rule of thumb, are the more complex ones
trying to compensate for frequency drift, or maybe eliminate higher
harmonics? how efficient and/or stable are the simple transmitter
schematics?

2. other than frequency range, what characteristics are you concerned
about when trying to match a transmitter to an amp?

3. without an amp, couldn't you still run the signal to an antenna and
it would be a weak transmitter? all the amp does is increase the
voltage and current supplied to the antenna, correct?

4. for an FM transmitter, does the modulation occur to oscillator
directly, or is the oscillator's signal modulated after "leaving" the
oscillator? i guess what i'm asking is whether or not there is an input
to the oscillator, or is it just an "output only" frequency generator?

thanks!
jason

Hi Jason

Nice questions, let me try to answer a few ..

<razorbladeshoes@gmail.com> wrote in message

> schematics?

One obvious thing is that CW transmitters tend to be simple, SSB transmitters complex. But there are a thousand design variables. One big one is the complexity of the ICs employed. Today you can have a very stable VFO with just a few parts. You tend to pay a little bit of a price in phase noise, but frequency drift is not an issue. With an analog VFO, you can add a lot of complexity trying to get around frequency drift, but phase noise is never an issue. Years ago, all you had was analog. A few years ago, DDS (direct digital synthesis) was complex and expensive. Today, analog VFOs tend on the expensive side! It is similar with amplifiers. In many radios, all, or most, of the PA is in a single brick, instead of a fistfull of parts. Ditto with almost everything up and down the chain.

Frequency is also an issue and again that is changing with technology. A few years ago, it was hard to get directly to VHF. You typically had several oscillators getting mixed up, frequency multiplied, etc. This was especially true if you had an analog VFO because it is very hard to get stability at VHF, and multiplying the frequency also multiplies the drift in an analog VFO. There are still reasons you might want to do some mixing up to get to VHF with a DDS VFO, but DDS parts up into the gigahertz range are now cheap parts.

It was only a few years ago that a DDS VFO cost hundreds of dollars. Today you can buy a chip with a VHF synthesizer and amplifier and modulator for less than the tuning capacitor in an analog VFO.

> 2. other than frequency range, what characteristics are you concerned
> about when trying to match a transmitter to an amp?

If you are buying commercial, you are looking at price, of course, and expected reliability, along with power consumption. For SSB, you need the amplifier to be linear, which implies lower efficiency. For FM/CW you don't need linear, so the amp can be a lot more efficient. If you are designing the amp, then you are worrying about impedance mathcing, as well.

> 3. without an amp, couldn't you still run the signal to an antenna and
> it would be a weak transmitter? all the amp does is increase the
> voltage and current supplied to the antenna, correct?

Yes of course. There are times when you want a lot of power, but most of the time it really isn't necessary. Also, it is a lot easier to get antenna gain than power to the antenna, especially at higher frequencies. The need for power depends a lot on what you do, what frequencies you operate, and to a degree, what "floats your boat". If you are doing EME or HSMS, you need a fair bit of power - hundreds of watts, anyway. If you are chatting on the local repeater, typically a watt is as good as a kilowatt. Lots of folks called QRPers like to use very low power. For them the "legal limit" is five watts, but many try to see what they can do with milliwatts. The current miles/watt record is held by a guy who operated 40 microwatts over a 500+ mile path.

> 4. for an FM transmitter, does the modulation occur to oscillator
> directly, or is the oscillator's signal modulated after "leaving" the
> oscillator? i guess what i'm asking is whether or not there is an input
> to the oscillator, or is it just an "output only" frequency generator?

Typically you would modulate the oscillator, although these days, the audio may well be simply data to the synthesizer. However, because FM is typically done at VHF and higher, there may well be additional oscillators mixed with the modulated signal to get up into the VHF/UHF range.

Hope this helps

..

Good info to know. I was kinda looking around to make a (mostly) IC transmitter like that... (anything 70cm and under). Are you aware of any chip PN's or schematics I could dive into to learn?

Thanks,
Dave

Analog Devices' parts are favored by hams. The greatest number of projects out there use the AD9850, but that part is a little older, and does not provide modulation input. Also, it is really only good up to about 30 MHz, you can push a bit past that but the power requirements explode and the noise goes up. Without any component changes it will go down to 1 Hz. Newer AD98xx parts are starting to get more attention, and some of those are useful up into the low 100's of MHz. The 99xx parts have more features yet.

TI has a TRF4400 which is a 440 MHz synthesizer with modulation and an amp (not much of an amp, tho!), and the almost identical 4900 for 900 MHz. Some folks have used these down to 6 meters. The TI parts have greater channel spacing than the AD parts, but that also reduces the frequency of the crystal or oscillator, which has a big effect on the power consumption. TI also has a 2050/1/2 which are synthesizers (I don't recall if they have modulation) up into the gigahertz range. I've been toying with using one of the TI parts as a VFO for an HF rig by using a prescaler to divide down the frequency (and consequsntly the spacing).

The AD parts are pricey, but AD is very good about samples. The TI parts are all in the five buck neighborhood. There are a zillion projects/kits out there based on the AD parts.

If you've ever built an analog VFO, these DDS parts are like black magic. They take little in the way of support circuitry, no fretting about layout, no spending weeks trying to work out the temperature compensation, no moving around because you breathed on it, you just dial in the frequency you want and you are spot on.

i guess what i meant was more along these lines: you need to make sure
the peak-to-peak input voltage and current capabilities of the input is
matched with the amp, right? or does the amp have a lot of leeway in
those regards?

> > 4. for an FM transmitter, does the modulation occur to oscillator

just to make sure i have it straight, if i were to transmit a sine wave
at 146mhz, anyone listening in on 146 mhz wouldn't hear anything
(except maybe less noise than usual). if i were to vary the frequency
between 146.0001 and 145.9999 at a rate of 100hz, then anyone recieving
would hear a quiet 100hz tone. now if i were to vary the frequency

between 146.001 and 145.999 (holding all previous listeners constant), then anyone listening would hear a much louder tone...correct? or am i not understanding it yet? ;-)

thanks again for the help!
jason

> those regards?

Actually, no. Typically the amp doesn't have a lot of flexibility there,
but in general the exciter does.

In amateur practice, the impedance of almost anything that connects together
at RF is 50 ohms or converted to 50 ohms. Given that, the power level then
converts directly to voltage and current.

Typically, HF exciters have a lot of range in output power. The FCC
prohibits the sale of HF power amplifiers having a required drive of less
than 80 watts. Since most HF exciters have 100 watts out, the required
input power of HF amps is rarely specified, since it will almost always
match almost all exciters. I don't think other countries have the same
rules, but the FCC also requires that the amps cannot easily be modified to
accept lower drive, so it is expensive for manufacturers to make amps
differently for different markets, since that typically would require a
complete redesign.

On VHF, it's a little different. Most VHF exciters only have a few output
power settings. VHF amps generally specify the input power, and typically,
it will be a fairly wide range. But still, if you want, say, 200 watts at 2
meters, you would buy a different amp for a 5 watt HT than you would for a
50 watt mobile.

> just to make sure i have it straight, if i were to transmit a sine wave

> between 146.001 and 145.999 (holding all previous listeners constant),
> then anyone listening would hear a much louder tone...correct? or am i
> not understanding it yet? ;-)

That is exactly right.

There is a weird behavior of FM receivers called the "capture effect". A
signal of sufficient amplitude at the input of an FM receiver cose to where
the receiver is tuned will totally quiet the receiver. In an AM, CW or SSB
signal, the amplitude is converted to audio almost directly. As a result,

noise on the input appears as noise on the output.

FM is different, though. In FM, we want to hear the frequency modulation. When there is no signal, we hear the detector randomly wandering around trying to interpret the noise as signal, but the amplitude of the noise really has no effect. Once a signal is detected that is strong enough for the detector to follow, the detector follows the signal and there is no more noise. To exaggerate this effect, most FM receivers amplify the signal so much that the amplifiers become saturated and amplitude variation in the input signal is clipped (well, softly clipped), so that the later stages of the receiver see the same amplitude. This is different than AM/SSB/CW where it is the amplitude changes you are looking for.

This is one of the reasons that FM signals have so much higher quality ... any noise is actually a result of noise in the receiver (or transmitter) rather than the atmosphere. With other modes, not only can you hear the atmospheric noise, but at lower frequencies, the atmospheric noise is many times higher than the noise inherent in the receiver.

The other reason is bandwidth. In amateur practice, FM signals are 5 kHz wide, compared to about 2.5 for SSB. In commercial practice, FM signals are wider still.

There is another "gotcha" in your description above. If you vary the carrier at, say, 1000 Hz, from say, 146.999 to 147.001, the actual bandwidth will be somewhat wider than you expect, and it will be dependent on the frequency of the modulation. I know this doesn't make sense, it has to do with some weird math. If you studied Fourier series back in school it was some abstract mathematical thing that had nothing to do with the real world. Well, guess what. Fourier has everything to do with radio! The result is that to stay within the 5 kHz bandwidth, the highest modulating frequency has to be somewhat lower than 5 kHz. This is one reason why the FCC prohibits amateurs from broadcasting music; reasonable fidelity of music requires higher bandwidth than voice.

..

Considering the fact that the last used pc I bought (p3-500) only cost $20
including a hard drive and sound card, I could have saved $8.95 by going the
sound card route. Depending on how good your source of obsolete computers
is, you can even get them for free. The pc can then also be used for PSK31
or any other use as well. As long a portability isn't an issue the pc can
stand in for quite a bit of hardware.
thanks, John.

Hello Gang,

I've got a crystal (7.155 mhz) that I need to use at half frequency. I decided to pump it into a flip flop, but I'm having an awful time using 2n3904 transistors. The triggering seems to be a very challenging design issue.

Anybody have any thoughts, (or other ideas for halving frequency)?

Lack of info. What kind of OSC? What kind of FF? Is there an
amp/buffer between the OSC and FF?

Generally this is usually a non problem as at 7mhz most flops are easy
to drive. Typical line up I use for this is a 2n3904 osc (any type),
a capactor coupled 2n3904 common emitter amp with a 1k collector load
and about 100 to 300K resistor between the collector and base to bias
it and couple that into the clock input of a 74LS74/74HC74 wired as
/2 or other config as needed. I also try to bias the flops clock
input to about half the VCC for better results. I've never had this
fail and it works fine to about 30-50mhz depending on FF used.

Yes, there is a trigger. Here is the schematic.
http://mysite.verizon.net/nonobar/circuit.jpg

There's actually a capacitor coupling the trigger pulse into the diodes (I forgot to show it).

The two bias resistors going to -15 are critical as are the commutating capacitors (not shown) across the 3.3k resistors.

It wants to work, but in a very unstable manner. I think I simply may be taxing the rise times of the 3904s.

Pete

You built the divider out of discrete transistors and steering diodes?
Running this sort of divider at 7 MHz will be marginal... some "speedup
caps" in parallel with the base drive resistors may help.

> or other ideas for halving frequency?

74HC74.

Tim.

1512. Schematics needed

Newsgroup: rec.radio.amateur.homebrew

I am looking for schematics for a few SCADA type transceivers I recently purchased as surplus.

I would like to get the schematics for the transceiver so I can modify them to work within the Amateur radio frequencies.

The transceivers I have currently operate on 172 MHz.
Markings on the transceiver are as follows:
Model # 030261-0114
Unit GND

Please let me know if you are able to help with this matter.

Thanks

1514. HELP!!! Diamond HF Dipole

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-12 12:33:10 UTC
From: andreantunes@sic.pt
Message-ID: <8bf084a1.0503120433.1e6e8907@posting.google.com>
Source record: 19947

Hi all,

I have an "old" W-8010 Diamond antenna that don't use anymore.
Everything is in very good condition.

I would like to transform this antenna into a W-735.

This means that I would like to take my BU-50 balloon and the two 80m
traps from my W-8010 and make an antenna just for 40 and 80 meters.

Would like to know if any of you guys know if this is possible, and if
so, what would be the size (length) of the wires.
Also, would like to know if the 80m traps are the same.

Any help is much apreciated.
Best Regards,

Andre Antunes

Anyone familiar with the Metheny Corp Madison, IN Model LJM-RB DTMF decoder board? I have two of these on a used VHF Engineering RPT-144 repeater I picked up.

I would like to find the schematic for this board.

Thanks much,

-Jim

be
>taxing the rise times of the 3904s.

The legacy transistor 2N3904 (and 2N3906) aren't "taxed"
any rise times. They are old workhorse transistors
which will work on up to 30 MHz (f_t is 150 MHz or
better)...provided the biasing AND the rather large
base-emitter capacitance is compensated. A good text
(also a "legacy" one) is Millman and Taub's "Pulse,
Digital, and Switching Circuits" which has much good
basic information on discrete device non-linear-
operation circuits.

The -15 VDC supply isn't necessary nor is it "sensitive"
if the trigger-switchover voltages are selected with
reasonable care. Ten percent tolerance resistors can
do the job with a single-rail supply of +5 VDC.

The "commutating" capacitors (common term is just
"speed-up") across the collector-to-base resistors
MAY be critical since those compensate for the base
to emitter capacitance and thus set the high frequency
response in that part of the circuit.

Since +5 VDC supply is there, one or two Schmitt
trigger inverters or gates from the oscillator output
(74HC family, for example) to a 74HC74 dual D F-F
will work fine. A quarter for each device and there
will be gates and a flip-flop left over to use
somewhere else. No sweating out component values
for discrete device circuits, response of the 74HC
devices known and dependable.

For that matter, the crystal oscillator itself can use the remaining inverters of a Schmitt trigger hex inverter. An ordinary non-Schmitt inverter (74HC04) can do the oscillator and squaring-up task as well. No sweat on that.

Does anyone here remember the simple CW transmitter that used a 6146 as a keyed ocillator? It would put out about 60 watts. There was a very low current light bulb in series with the crystal to limit the current that could flow in the crystal circuit. I think it was in the 1959 or 60 HANDBOOK. I used a gaseous regulator tube on the screen. It didn't chirp too badly.....Analog VFO's yes now there is a fun project!

I wouldn't use one of those, unless it was a lower frequency. At 7MHz,
straight versions of those ICs are pushing their limits. And it's
not as if better CMOS devices haven't come along in the 35 years or
so since that series was introduced.

Never meant to infer that old stuff doesn't work (and sometimes well)
after all some of the guys on this NG also frequent the antique radio
NG. I wasn't aware that the 1n21/23 series diodes were considered
state of the art until the late 70's/early 80's though. Actually
in the 60's many hams used PAR-AMPS (which are a kind of MASER!)
in front of their diode mixers. (I remember an article in QST from
the 60's on a reflex klyston pumped par-amp using an early
varicap diode).

The nearly paranoid precautions taken by this poster to protect his identity would make be very suspicious about dealing with him on a $750 item, particularly since he has 2 negative eBay feedbacks on his record -- one of which labels him a "fraud". Also, I would not like to be on the eBay record for having dealt with sellers who have "private sales".

What is this guy trying to hide, and why?

Doesn't he realize that any eBay user can easily learn his identity based on his eBay sellier ID, and that the content of his "private" sales are not all that private. Still, not worth the efforts. It makes more sense simply to play it safe and avoid eBay sellers of this type.

Harry C.

Source record: 19861

I'm the youngster -- 1938.

Seems that I'm in the right circle of 'Old Farts' to ask: Has anyone a data sheet available on the 723A/B Reflex Klystron? These (along with the 1N21 diodes) were used in the AN/APS-3 RADAR and since have found use in physics demonstration devices, and to a limited extent ham radio (with modifications). It is basically a 3-cm or 10-GHZ oscillator.

I have a pin-out, but not a full-blown data sheet. Can anyone help me out on this?

Thanks in advance, and 73's.

Harry C.

p.s. Evidently a large number of 723A/Bs were produced by Raytheon, but in spite of a 15-year employment with the Raytheon Company, I've never been able to locate a data sheet. Evidently devices of this type were heavily classified during WWII, and consequently most of the documentation was classified and eventually, in accordance with security instructions, destroyed.

1529. Re: Plan 9 from EMI space?

Source record: 19862

Something that is (and I'm assuming that you're posting about a ham radio application) an important question regarding EMI is what kind of antenna are you using, how far is it away from your appartment EMI sources, and what sort of shielded feed are you using to connect your equipment with the antenna?

>From your post, it sounds like most of your EMI sources are in your appartment. You want to have your antenna(s) as far away from these noise sources as possible, as well as shielding the feed from the antenna to your equipment as much as is possible. Generally speaking, coax like RG-8U makes a good antenna feed, but in extreme EMI cases a coax with double shields is a good investment.

Since most of us have the same EMI producing devices in our homes as do you, I'm not sure why you're having any more of a problem than the rest of us, unless of course you haven't yet installed a good, outside antenna system with a properly engineered feedline. If this is the case, no amount of appliance and power line noise suppression will achieve the results you are looking for.

The band in question is AM and the 13135 is an FM chip with discriminator. A perfectly fine lineup for your needs is any of the DBM's from Mini Circuits Labs or build you own with a few diodes and a couple of ferrite beads, the MC 1496/1596 is still very much available, even made the transition to SSOP if your tastes run to small and surface mount. Low side injection with an AD 9851 or high side with a 9951 DDS. With the channel spacing up there, a selection of an inexpensive Murata filter will do your selectivity, and audio is a VERY wide selection.

thanks again for the help...your answers led me to a couple other
questions, if i may ask?

xpyttl wrote:

> In amateur practice, the impedance of almost anything that connects
together
> at RF is 50 ohms or converted to 50 ohms. Given that, the power
level then
> converts directly to voltage and current.

so if i were to design a transmitter around an COTS amp, how would i
determine what i needed to "drive" it at, in terms of voltage? if i
have 3 variables (V, I, and R) then i'd need to know 2 of the 3, then i
can solve for the third... as it is, i only know R...?

> This is one of the reasons that FM signals have so much higher
quality ...
> any noise is actually a result of noise in the receiver (or
transmitter)
> rather than the atmosphere. With other modes, not only can you hear
the
> atmospheric noise, but at lower frequencies, the atmospheric noise is
many
> times higher than the noise inherent in the receiver.

so i imagine people can do CW over FM, but does it usually occur on (I
guess what would be called) a simplified AM transceiver? either a
signal's present or not?

also, when people refer to ASK and FSK, is ASK basically an audio
output that's been sent over FM? and FSK is more like CW, only to a
receiver that can monitor both mark and space (0 and 1) frequencies?

thanks again!
jason

I believe he meant AFSK (audio frequency shift keying) vs FSK (frequency
shift keying).

Well I might have a Ham Radio Handbook with some data in it but I don't
have a "data sheet".
I can tell you that about 250 Volts on the shell and minus 75 to 150
volts on the repeller will work.
You have to adjust the repeller voltage to get the maximum power. Also
the repeller voltage changes
the frequency. And if you adjust the mechanical frequency then the
repeller voltage must be changed.

Never never never run the Klystron without the minus repeller voltage

Hope that is useful.

yes, that is what i meant. i didn't even know amplitude shift keying
existed.

am i correct about afsk being audio tones transmitted over FM, while
fsk is just alternating between two non-modulating frequencies?

This group has the most complete collection of modifications, usage tips, links to related websites, documentation, and photos along with a user survey and a message forum (3250 messages archived) to help you get the most fun and DX out of your Realistic / Radio Shack DX-394, DX394, DX 394.

Over 90 mods and tips now listed plus a dozen on the To Do or Wish List. More mods than for any other general coverage receiver! Thoroughly documented with a Master Index. If you like to tinker with radios, I know of no other recent model that lends itself to as much fun in this arena as the DX-394. Great platform for learning radio-electronics. Always 1 or more FA on eBay.

Active & friendly user community now with over 800 members. Some members are keen short wave listeners; others are into AM DXing and a few enjoy long wave. Many experiment with antennas and some are ardent modifiers - customising and souping up the rig as hot rodders would do with cars. You'll find lots to interest you and help get the most out of your radio.

Mods & Tips since 17 Oct 04:
- RF: FRONT END PROTECTION FROM HAM TRANSMITTER

- RF: OVERLOAD MITIGATION - WIDEBAND PRESELECTOR

- ANT: WHIP - REPLACEMENT

- RF: OVERLOAD MITIGATION WITH OUTBOARD ATTENUATOR

- AGC: HOTTER S-METER AND AGC ACTION

- DEMOD: SYNCHRONOUS AM DETECTOR

- OSC: UPGRADE STABILITY OF 2nd LOCAL OSCILLATOR

- RF: SHIELDING WITH ALUMINUM DUCT TAPE or STEEL TAPE

- CONTROL: CUSTOM MAIN TUNING KNOB

- AUDIO: ENHANCED ANTI-CHUFF MOD AKA MODE CHANGE CLICK BLANKER

All here at:
http://groups.yahoo.com/group/�RADIOSHACKDX394/

That's pretty close, but not exactly on target.

AFSK can be used on top of either AM or FM. In amateur systems it's
most commonly used with FM.

FSK shifts the carrier frequency... a process which counts as a
modulation. The amount of frequency shift (in Hz) and the rate at
which you shift it (also in Hz) vary a lot from one usage to another.
There are both narrow-band and wide-band FSK modulations in use.

thanks! also, i was just reading about mixers... and getting confused.
i've run some matlab programs to figure out how you can take something
at frequency x and frequency y, and end up with an output of frequency
(x-y). one transmitter's mixer i saw took a 160mhz and 14mhz input to
get a 146mhz output. adding or multiplying them together certainly does
not yeild 146mhz. so how does that work?

thanks for the help!

You are partly correct. If audio tones are fed into the microphone input (audio stages) of an AM or FM transmitter you are generating AFSK. If an audio tone is fed into a SSB transmitter it will generate a single output frequency. If the tone is switched off and on , it will be received as a CW transmitter being keyed off and on. Some newer transceivers generate CW this way. If the tone is shifted in frequency , the output will be a carrier shifted the same ammount. This is received the same as a FSK transmitter. You can get the same effect if you have a crystal controled transmiter and switch a capacitor across the crystal to change the frequency.
There is almost no way to tell the differance between the two. If 100% pure tones are used and everything else it 100% correct then there is no differance in the transmitted signals. As always nothing is 100% and you can tell the differance with very close and strong signals. This is still close enough it does not matter.

You need a nonlinear function in order to get mixing behavior, and
create the sum and difference frequencies.

If you just add (e.g.) sin 160x and sin 14x, you end up with a simple
sum of sins, and no other frequencies show up - ordinary superposition.

Run the resulting sum through a nonlinear function (e.g. square it, or
take the square root, or clip it whenever its absolute value exceeds
1.0, or something like that), and take a look at the frequency content
of what you get as a result.

1545. Wire gauge for 117 VAC circuit?

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-14 04:24:54 UTC
From: Hatfield <utility_infielder@earthlink.net>
Message-ID: <1110774294.380148.179590@o13g2000cwo.googlegroups.com>
Source record: 19878

Hello, in the past, my from scratch contruction has been @ 12 volts.
Now I am going to try a built from scratch tube project which uses 117
volt main xformer, also 117 v on the plate; the whole radio circuit
will be fused through a 2 amp fuse.

What gauge of hook up wire should I use for the project's circuitry,
for safety's sake, I don't want to use too small.

Thanks for any advice.

>I believe he meant AFSK (audio frequency shift keying) vs FSK (frequency
>shift keying).

The ITU emission designators for some digital modes and some typical
usage:

* A1A On/Off keying for manual reception (Morse)

* A1D ASK, Amplitude shift keying. The only recent use I have seen
is in some 433 MHz SRD (Short Range Devices)

* F1D Pure FSK (RTTY is classified as F1B)

* F2D Audio subcarrier modulated by amplitude or frequency (e.g.
1200 bit/s AX.25 packet) modulating an FM transmitter

* A2A Audio subcarrier on/off modulated by Morse code modulating
an AM transmitter (e.g. aeronautical beacons in the LF band)

* A2D Audio subcarrier modulated by amplitude or frequency
modulating an AM transmitter

* J2A Audio subcarrier on/off modulated by Morse code modulating
an SSB transmitter (many amateur multimode rigs)

* J2D Audio subcarrier modulated by amplitude or frequency (e.g.
300 bit/s AX.25 packet) modulating an SSB transmitter

On the air A1A and J2A are equivalent.

On the air F1D and J2A are equivalent and can be generated and
detected in both ways.

I hope this clarifies some of the issues.

The gauge needed is not related to voltage, but to current. Once you
have decided what current each winding must carry, you can choose the
wire size for that current.
Here is a wire table that recommends wire size versus amps that should
serve.

The wiring insulation determines the safe operating voltage -- buy wire
who's insulation is rated for the voltages you want to work with. It
should be readily available, so there's no reason to cut corners here.

If you are asking this sort of question, then I would seriously doubt your ability to complete a HV project without killing yourself - have you read the section "Electrical Safety" in the ARRL handbook - can recommend it as a good general text on all things electronic.

The size you need is the same as nearly every mains operated appliance in your house - go to your local hardware store and buy as much as you need - dont know what current ratings you use in the USA, but 10 amps is generally more than sufficient for nearly everything. Do you know how to terminate the power plug safely , and properly wire it to the radio you are building? - it is important, and again the ARRL handbook covers such safety issues.

Good luck with the project, you are starting to get into "real" radio.....

Thanks for the suggestions. I ordered the Ramsey kit as a way to have something to play with for now.

Next step is to lash together either a PLL-VCO combo or DDS to control the tuning from a cheapo processor (e.g. PIC). Any suggested starting points for this would be much appreciated (for example "National LMX2xxx plus Minicircuits xx" or "forget that, AD DDS is better because.....")....8-).

The guts of the Ramsey widget consists of an SA602 and an MC1350 (single conversion with 10.7 Mhz IF). Potential ways to "improve" upon this???

Thanks again.
Bill (RF Newbie - but willing to learn 8-)...

Especially when the OP states that he'll be using "117 v on the plate"!!
Sounds like a 'design' more dangerous than the old AC/DC radios!

1552. B- on RF Amp

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-14 18:37:26 UTC
From: hanavin@stimpy.eecis.udel.edu
Message-ID: <d14ll6mmt1@dewey.udel.edu>
Source record: 19885

I was wondering what the advantges are of having B- on RF amplifer instead of just grounding it? I think it may be that the plate meter doesn't have a huge voltage across it, that can arc to ground. But what if you are using a triode and just have a cathode meter, no plate meter is the B- necessary? Any comments are appreciated.

thanks-Chuck (W3FJJ)

That is not correct either. AFSK is used extensively with Amateur Radio
digital systems, such as PSK-31, RTTY, even CW can be and is generated
using AFSK. And the modulation METHOD is not important. It can be either
Amplitude or Frequency Modulation.

1554. SERIOUS MONEY OPPORTUNITY-$5 INVESTMENT-HIGH RESPONSE RATE-QUICK RETURNS

Newsgroup: rec.radio.amateur.homebrew
Date: 2005-03-14 21:23:04 UTC
From: feedbackzz@yahoo.com
Message-ID: <1110835384.932175.78420@f14g2000cwb.googlegroups.com>
Source record: 19887

Follow the directions below and you could
have $5000 in your PayPal account in 2 weeks.
There is a very high response rate in this
program because of its low investment, high
yields, and quick return. If you are a skeptic
and doubt that the program will work, I urge
you to give it a try anyway! It REALLY WORKS-
that is why so many thousands are involved in
programs like it. Don't miss this chance.

If you achieve only moderate success, your
PayPal account will still have several hundred
dollars in it within the next couple weeks.
If you actively promote the program, you could
soon have $8,000 in your PayPal account.

SIMPLE: All you need is $5 and a free PayPal
account. Pay $5 to one person.

SECURE: PayPal (BBB member) handles all
transactions. No one sees your bank or credit
card information.

LEGAL: See Title 18, Section 1302 and 1341,
US Postal and Lottery Laws.
The details of this business make it legitimate.
You are using the Internet to advertise your
business opportunity. You have a mail order
business that collects email addresses from
people interested in home-based online business.
You provide a service-mailing list membership-
in return for a small fee. Treat your mailing
list as a business. Keep accurate records,
declare your income, and pay income tax on it.

INSTRUCTIONS

STEP 1: COPY and PASTE this letter onto a
blank notepad file. SAVE as a TEXT FILE.
Keep it for the next time you need the
program.

STEP 2: Get a free PayPal account
(5 minutes setup time) at www.paypal.com.
Register for a PREMIER account (not a

PERSONAL) so that others can send money
to your account.

STEP 3: Using your PayPal account, send $5
(US DOLLARS) to the email address (PayPal
account) in position #1 of the list below.
PayPal will ask for a payment type-select
SERVICE. In the SUBJECT area, enter
"Please add me to your mailing list"
(this is very important). If you prefer
that your email address not be given to
other mailing list businesses, enter
"Please add me ONLY to your mailing list"
in the SUBJECT area. In order to send
money, you can deposit $5 into your PayPal
account with your own credit card, use
your bank account, or register for the
PayPal credit card.

IMPORTANT: IN ORDER FOR YOUR BUSINESS
TO WORK, YOU MUST BE HONEST AND SEND $5.
The mailing list business remains successful
due to the honesty and integrity of those
involved. $5 is a very small investment,
especially when you are about to receive
many times that much! If we are all honest,
we will all make money.

STEP 4: After you send your $5, remove the
address from position #1 of the list below.
Put the address in position #2 into position
#1. Put your own email address (PayPal
account) in position #2. Some engines will
automatically hide part of an email address
when the letter is posted in a newsgroup.
It may look like this:
yournam...@wherever.com

To avoid this complication, enter your
email address using 2 separate lines,
like this:

2) yourname (press ENTER on your keypad)
@wherever.com

(If you ever encounter the dots, click on
SHOW OPTIONS at the top of the letter, then
click on REPLY. Scroll down through the
original letter to find the full addresses.)

Both people on your list have already bought
mailing list memberships for $5! The program

is working! Note: If you put your name in position #1, you will not receive money from the hundreds that other members find.

CURRENT PAYPAL ACCOUNTS:

1) cwhatton22
@charter.net

2) feedbackzz
@yahoo.com

STEP 5: COPY and PASTE this letter (with your address in position #2) in emails to at least 60 newsgroups, chat sites, discussions, message boards, etc. It takes less than a minute to post the letter. The more you post, the more money you can make. People will see the letter heading as they scroll through the list of postings in a particular group. PASTE the heading below into the subject area of your email (you can also write your own heading):

SERIOUS MONEY OPPORTUNITY-
$5 INVESTMENT-HIGH RESPONSE RATE-
QUICK RETURNS

Use the search engines (Internet Explorer, yahoo.com, google.com, altavista.com, excite.com) to find sites. Search for moneymaking forums, moneymaking message board, money chat, employment message board, business message board, business discussions, etc. You can create your own free webpage (try webspawner.com, cmlb.net), then post links to your site. Try posting a notice on community and college bulletin boards to direct people to your webpage.

THIS BUSINESS WORKS

When your name reaches position #1 (usually in less than a week) it will be your turn to receive $5 deposits. If you personally find 20 interested people, and they each find 20, you make $2000. If you find 40 people, and they each find 20, you make $4000. Remember that the response rate is very high. Since there are only 2 names on the list, you can expect 80% of your profits within 2 weeks.

Participants who actively promote their mailing
list average between $5,000 and $8,000 and
receive the funds within 3 weeks.

Relieve your financial stress NOW!
Become a part of the mail order business and
help people to help people.
This program is about helping each other!

That is a fair question, and one which is frequently asked.

Look up the trig identity for (sin a)(sin b). Let a and b each be in the form wt [w stands for greek lower case omega], so a = 2(pi)f1(t) and b = 2(pi)f2(t) where f1 and f2 are your two frequencies in Hz. Do the substitution & algebra on the identity, and then I think you'll see where the signals at the sum and difference of frequencies f1 and f2 come from. :-)

The name "mixer" can be a little misleading.....it doesn't necessarily just sum the two inputs in a linear fashion (by just adding them, like a kitchen mixer combines the ingredients for a cake) but there is also an element of non-linearity in the electrical network.

Depending on the nature of the non-linearity, mixing can also generate other higher-order products, like signals at 2f1+f2, 2f1-f2, etc. Whether this is good or bad depends on your particular application. For example, do some reading on "intermod".

It would be easier to convert an old AM/FM tuner or AM/FM stereo and you can get them all over the place for a few bucks. Tube types are collector items but the older SS ones with discreet components and ICs are considered pretty much obsolete. Find one with an open tuning cap and remove a plate or two, or rewind the coils (too much work) or replace the enclosed tuning cap with an open one. Add an 11 mhz osc and use the 455Kc IF stage and AM detector.

Firstly, 108 to 118 MHz is the international civil aviation radionavigation band. It's not all that interesting to listen to unless a local tower is also repeating voice comms over a VOR or Localizer radionav transmitter nearby on the ground. The civil aviation voice band is 118 to 137 MHz.

Secondly, the MC1350 gain block is available from Jameco (it is still made after buying all the masking and stuff from Motorola). You can get MC1349s, a slightly higher gain version from Dieter Gentzow at Kitsandparts.com; I got 18 of them just before Christmas along with some other good parts. Good service from Kitsandparts, great source of toroid cores.

There's still lots of legacy ICs available out there but you may have to search for sources.

If you are trying to build something at VHF, you will need some reasonably accurate signal sources to check out the receiver. That's not a trivial task unless all you want is to carbon-copy some regen or super-regen tuned-by-a-single-variable sort of receiver.
